Notice to Contributors

uired for each paper submitted, except for comments; such fees will be waived for check or money order, made payable to the American Sociological Association, mission. The fee must be paid in order for the review process to begin.

r is generally ten (10) printed pages or thirty (30) typed pages. However, the *ASR* is ts up to fifty (50) typed pages in length for review. We also are interested in receiving ch and Notes Section.

the review of manuscripts, keep identifying material out of the manuscript. Attach a cover institutional affiliation and acknowledgments, and provide only the title as identification on stract.

ions Policy: Submission of a manuscript to a professional journal clearly implies commitment rnal. The competition for journal space requires a great deal of time and effort on the part of ose only compensation for this service is the opportunity to read papers prior to publication on associated with discharge of professional obligation. For these reasons, *the American ciation regards submission of a manuscript to a professional journal while that paper is under r journal as unacceptable.*

AND PREPARATION OF MANUSCRIPTS

(4) copies and retain the original for your files. Copies may be Xerox, mimeograph or multilith; but no s.

2. Enclose a stamped self-addressed postcard for acknowledgment of manuscript receipt. *Manuscripts will not be returned.* Please do not send your original copy.
3. All copy must be typed, doublespaced (including indented material, footnotes and references) on 8½ by 11 inch white opaque paper. Lines must not exceed six (6) inches. Margins must be a minimum of one inch.
4. Include four (4) copies of an abstract of no more than 150 words.
5. Type each table on a separate page. Insert a location note at the appropriate place in the text, e.g., "Table 2 about here." Send copies, retain originals.
6. Figures must be drawn in India ink on white paper. Send copies, retain originals.
7. Clarify all symbols with notes in the margins of the manuscript. Circle these and all other explanatory notes not intended for printing.
8. Footnotes should not be placed in the body of the text. Type them (doublespaced) and attach them as a separate appendix to the text. Number them consecutively throughout the text. Footnotes are to be kept to a minimum and used only for substantive observations. Source citations are made within the text rather than in footnotes.
9. Acknowledgments, credits and grant numbers are placed on the title page with an asterisk.

REFERENCE FORMAT

A. *In the text:* All source references are to be identified at the appropriate point in the text by the last name of the author, year of publication and pagination where needed. Identify subsequent citations of the same source in the same way as the first, not using *"ibid.," "op. cit.," or "loc. cit."* Examples follow:

1. If author's name is in the text, follow it with year in parentheses. [". . . Duncan (1959) . . ."]
2. If author's name is not in the text, insert, in parentheses, the last name and year, separated by a comma. [". . . (cf. Gouldner, 1963) . . ."]
3. Pagination (without "p." or "pp.") follows year of publication after a colon. [". . . Kuhn (1970:71)."]
4. Give both last names for dual authors; for more than two use "et al." in the text. When two authors have the same last name, use identifying initials in the text. For institutional authorship, supply minimum identification from the beginning of the complete citation. [". . . (U.S. Bureau of the Census, 1963:117) . . ."]
5. Separate a series of references with semicolons and enclose them within a single pair of parentheses. [". . . (Burgess, 1968; Marwell et al., 1971; Cohen, 1962) . . ."]

B. *In the appendix:* List all source citations by author, and within author by year of publication, in an appendix titled "References." The reference appendix must be complete and include all references in the text. The use of "et al." is not acceptable in the appendix; list the names of all authors. (See A. 4. for text format.)

If there is more than one reference to the same author and year, distinguish them by the letters, a, b, etc. added to the year. [". . . Levy (1965a:331) . . ."] Give the publisher's name in as brief a form as is fully intelligible. For example, John A. Wiley and Sons should be "Wiley." If the cited material is unpublished, use "forthcoming" with name of journal or publisher; otherwise use "unpublished."

Use no underlining, italics or abbreviations.

Examples follow:

1. *Books:* Jud, Gerald J., Edgar W. Mills, Jr. and Genevieve Walters Burch
   1970 Ex-Pastors. Philadelphia: Pilgrim Press.
   U.S. Bureau of the Census
   1960 Characteristics of Population. Volume 1. Washington, D.C.: U.S. Government Printing Office.
   Bernard, Claude
   [1865] 1957 An Introduction to the Study of Experimental Medicine. Tr. Henry Copley Greene, New York: Dover.
2. *Periodicals:* Conger, Rand
   Forthcoming "The effects of positive feedback on direction and amount of verbalization in a social setting." Pacific Sociological Review.
   Merton, Robert K.
   1963a "The ambivalence of scientists." Bulletin of The Johns Hopkins Hospital 112:77–97.
   1963b "Resistance to the systematic study of multiple discoveries in science." European Journal of Sociology 4:237–82.
3. *Collections:* Davie, M.
   1938 "The pattern of urban growth." Pp. 133–61 in G. Murdock (ed.), Studies in the Science of Society. New Haven: Yale University Press.

See recent issues for further examples.

SCOPE AND MISSION OF AMERICAN SOCIOLOGICAL REVIEW: The *American Sociological Review* publishes work of interest to the discipline in general, new theoretical developments, results of research that advance our understanding of the most fundamental social processes, and important methodological innovations. Like other publications of the Association, emphasis is given to exceptional quality. Unlike the more specialized journals of the Association, the *American Sociological Review's* primary focus is on whatever has the most general bearing on the knowledge of society.

Concerning manuscripts, address: Editor, *American Sociological Review,* Department of Sociology, University of Illinois, Urbana, Illinois 61801. (217) 333-6515.

The *American Sociological Review* (ISSN 0003-1224) is published at 49 Sheridan Avenue Albany, New York, bimonthly in February, April, June, August, October, and December.

Applications for permission to quote from this journal should be addressed to the Executive Office

Copyright © 1980 American Sociological Association.

Annual membership dues of the American Sociological Association, $20–$120 ($10 of this amount may cover a subscription to the *American Sociological Review*); Associate, $25; International Associate, $25; Student Associate, $12.

Application for membership and payment of dues should be made to the Executive Office. Subscription rate for members, $10; nonmembers, $15; institutions and libraries, $30; nonmember students, $10. Single issue, $4.

New subscriptions and renewals will be entered on a calendar year basis only.

Change of address: Six weeks advance notice to the Executive Office and old address as well as new are necessary for change of subscriber's address.

Concerning advertising, changes of address, and subscriptions, address: Executive Office, American Sociological Association, 1722 N Street, N.W., Washington, D.C. 20036.

Claims for undelivered copies must be made within the month following the regular month of publication. The publishers will supply the missing copies when losses have been sustained in transit and when the reserve stock will permit.

Second class postage paid at Washington, D.C. and additional mailing offices.

AMERICAN SOCIOLOGICAL REVIEW

A NEW THEORY OF DISTRIBUTIVE JUSTICE*

301.05
Am 35

GUILLERMINA JASSO
U.S. Immigration and Naturalization Service

American Sociological Review 1980, Vol. 45 (February):3–32

This paper proposes a new theory of distributive justice, one that is fully mathematized and fully testable. The theory describes how choices made by individuals (about which goods to value, which social aggregates to form, and what conditions to regard as just or fair for themselves) combine with two objective structural features—the actual distributions of goods and their intercorrelations—to produce the sentiment of justice in the individual. The theory views social relations as a meeting of justice sentiments. Hence, a social aggregate is characterized by the distribution of justice sentiments experienced by its members; and the social aggregate's characteristic social facts are approximated by the parameters of the distribution of justice sentiments, such parameters as the proportion who feel unjustly underrewarded, the Gini's mean difference, the lower extreme value, the overall mean, and many others. By holding constant both the goods of value to the members of a social aggregate and the condition regarded by them as just or fair, it becomes possible to generate expected distributions of justice sentiments from knowledge of the actual distributions of goods, thereby enhancing the usefulness of the theory. In this paper, using three hypothetical distributions of goods (Rectangular, Pareto, and Lognormal), we generate the corresponding expected justice distributions—one negatively skewed Exponential, a family of positively skewed Exponentials, and a family of Normals—and evaluate many parameters of interest.

This paper proposes a new general theory of distributive justice, one which is fully mathematized and fully testable and whose explicit aim is the explanation and prediction of a wide range of empirical phenomena at both the individual and the social levels. This theory builds on the specification of the justice evaluation function which I recently proposed (Jasso, 1978).

That work describes an empirically induced justice evaluation function for the case of earnings, and suggests its generalization to the sentiment of justice about all goods of distribution. The proposed function claims that the justice evaluation varies as the logarithm of the ratio of the actual share of a good to the perceived just share. That is,

$$\text{justice evaluation} = \ln \frac{\text{actual share}}{\text{just share}}, \quad (1)$$

where the sense of justice is represented by the full real-number line, with zero representing perfect justice, the positive segment representing unjust overreward, and the negative segment representing unjust underreward. This function quantifies the common opinion that deficiency is felt more keenly than comparable excess. The function was shown to accord with perceptions of justice regarding earned income, based on survey data from a probability sample of adult respondents in private households (Jasso, 1978).

The present paper attacks two major tasks: (1) to embed the justice evaluation function in an explicit theory of justice; and (2) to specify behavioral consequences of the theory which will permit an independent test of it.[1]

---

* Direct all communications to: Guillermina Jasso; 15 Penny Lane; Baltimore, MD 21209.

This paper benefited from the substantive comments and editorial advice given by an anonymous *ASR* referee, by the editors of this journal, and, most particularly, by Murray Webster, Jr. I am also grateful to Ludwig Brand for advice on preparing the figures, to Morris Zelditch, Jr., Robert Nisbet, and Herbert Passin for comments on earlier versions, and to the Barnard College Research Committee for assistance in manuscript preparation of those versions.

[1] Comprehensive summaries of the literature on distributive justice have recently appeared (e.g., Cook, 1975; Walster et al., 1976; Jasso and Rossi,

The main features of the general theory of distributive justice proposed in this paper are as follows:

(1) The theory notices only the justice evaluations made by individuals about their own shares of goods. That is, it does not conceptualize the phenomenon of "disinterested outrage" over injustice suffered by others (see Berger et al., 1972:126, for a discussion of this issue).

(2) The general theory asserts the mathematical form of the justice evaluation function's two predictor variables, the actual term and the just term, but leaves exogenous their substantive content.

(3) The general theory asserts the combinatorial function for the experience of justice about more than one good at a time.

(4) The theory suggests that an individual may be characterized by the subjectively experienced magnitude of justice or injustice and by his/her time series of justice evaluations; it also suggests that phenomena observable in individuals vary with the instantaneous justice evaluation or with the parameters of the individual's time series.

(5) The theory suggests that a social aggregate may, at any point in time, be represented by the frequency distribution of the instantaneous justice evaluations experienced by individuals in the social aggregate; it also suggests that social phenomena vary as functions of the parameters of these instantaneous distributions. Variation in social phenomena over time can be understood by reference to changes in the distribution of justice evaluations.

Thus, the theory offers a unified view of human behavior, with the sense of justice a basic factor in the etiology of phenomena at both the individual and the social levels. In this paper, however, our main focus shall be on social aggregates and social-level phenomena.

I. THE GENERAL THEORY OF DISTRIBUTIVE JUSTICE

A. Preliminary Definitions

1. Goods are what people want.

They want goods not only for their own sake, but also for the sake of happiness (Aristotle [384–322 B.C.] 1952, *Nicomachean Ethics,* Book I, chap. 7). Goods may be described along several dimensions; the theory notices three:

a. primary versus *secondary*—Primary goods are goods that "every rational [person] is presumed to want" (Rawls, 1971:62). All nonprimary goods are secondary goods.

b. social versus *natural*—Social goods are goods whose distribution is controlled socially; natural goods comprise the more intrinsic attributes of the person, goods that are, as Rawls (1971:62) puts it, "not so directly under [societal] control." Rawls (1971:62) suggests that the chief social primary goods include "rights and liberties, powers and opportunities, income and wealth" and that the natural primary goods include "health and vigor, intelligence and imagination."

c. quality versus *quantity*—Quality-goods are nonadditive, nontransferable personal attributes, such as beauty, intelligence, or social honor; quantity-goods are additive, transferable possessions, such as wealth or livestock (cf., Campbell [1921] 1952:125). The most important measurement strategy contained in the present theory, and codified in the two Principles (to be discussed here), is based on this distinction between quality and quantity.

2. Just amount or level of a good.

This is the amount or level considered to be just by the person making the justice evaluation; that is, it is the denominator of the ratio in the justice evaluation function.

3. The Comparison Aggregate (CA).

This is a physical or conceptual aggregate that is used by humans when they locate their rank on a quality-good and when they calculate their relative share of a quantity-good.[2] The Comparison Aggregate is also used when humans form the just term for quality-good and when they express the just amount of a quantity-good as a just share.

1977; Robinson and Bell, 1978; Jasso, 1978; and Webster and Smith, 1978), and will not be repeated here. Our greatest debt is to the work of George C. Homans (1967; 1974) and of Joseph Berger and his associates (1972).

[2] Our concept of Comparison Aggregate is considerably wider than its ancestors (see Hyman, 1942; 1966; Merton and Rossi, 1950; Kelley, 1952; Festinger, 1954; Merton, 1957; and Berger et al., 1972), for it encompasses any aggregate used by an individual in comparison processes, whether or not it is a "group" and whether or not the individual is a "member."

4. The Social Aggregate (SA).

This is any physical or conceptual aggregate of humans who are mutually aware of each other and of the aggregate they form (Nisbet, 1970:81). (Notice that the Comparison Aggregate and the Social Aggregate may, but need not, be the same for a given justice evaluation situation. For example, a person may evaluate his/her statesmanship relative to the Comparison Aggregate, "all Presidents of the United States," in which case the CA cannot possibly be a Social Aggregate. On the other hand, this same individual may evaluate his/her statesmanship relative to the Comparison Aggregate, "all heads of government in February of 1978," in which case the CA may well be also a Social Aggregate.)

B. The Basic Part of the General Theory of Distributive Justice

To construct the theory, we begin by stating two orienting (metatheoretical) assumptions. We take as given that:

> (1) Self-appraisal is the elementary judgment made by humans about their endowments, attributes, and possessions, whether dealt them by nature and society or obtained by personal exertion.
>
> (2) Humans form notions of justice, of the just holding of the natural[3] and social goods—that is, about the just results of the natural and social lotteries and of personal exertions.

We then formalize the method for the measurement of the self-appraisals and the notions of justice and propose the mathematical relations between them. The measurement strategy is codified in two Principles and the mathematical relations in three Laws. The formal statement of the theory follows:

First Principle:
Ordinal Appraisal of Quality-Goods and Cardinal Appraisal of Quantity-Goods

The mathematical form of the self-appraisal differs according to whether the good is a quality or a quantity.[4] *With respect to quality-goods, humans locate themselves in the rank orders of goods in selected Comparison Aggregates, calculating for themselves an Actual Rank. With respect to quantity-goods, humans measure their amount of goods in the intrinsic units of the goods, calculating for themselves an Actual Amount.*

Second Principle:
Ordinality of Just Term for Quality-Goods and Cardinality of Just Term for Quantity-Goods

The mathematical form of the notion of justice, i.e., of the just holding of a good, differs according to whether the good is a quality or a quantity. With respect to quality-goods, the just term is measured as a rank score, termed the Just Rank. With respect to quantity-goods, the just term is measured in the good's own intrinsic units, termed the Just Amount.

First Law:
Comparison of Actual to Just Holding of Goods

Humans compare their actual holdings of goods to their notions of the just holdings by taking a ratio of the Actual term to the Just term; we call this the Comparison Ratio (CR). With respect to quality-goods, the Comparison Ratio is the ratio of Actual Rank to Just Rank; with respect to quantity-goods, the Comparison Ratio is the ratio of Actual Amount to Just Amount. The Comparison

---

[3] Philosophers and theologians have almost unanimously argued that justice terms ought not to be predicated about the natural inequalities (e.g., Miller, 1976:18). For Aquinas this became an important issue, for to admit that the natural inequalities are unjust is ultimately to impute injustice to their author. Rawls (1971:102) remains in this tradition—though possibly not for the same reasons as Aquinas, noting, "The natural distribution is neither just nor unjust. . . . These are simply natural facts. What is just or unjust is the way that institutions deal with these facts." On the other hand, Freud ([1929] 1952:788) in *Civilization and Its Discontents,* as a clinician alive to empirical sentiments, observed that "nature began the injustice by the highly unequal way in which she endows individuals physically and mentally, for which there is no help." Our theory accepts Freud's manner of speaking as an accurate description of the human sentiment of justice.

[4] The two Principles embody our answer to the argument between Homans (1967:66–7) and Berger et al. (1972:127) about whether humans care about ordinal or cardinal differences in their shares of goods. We find them both right. Our work has been only to distinguish the class of goods about which ordinal differences are important from the class of goods about which cardinal differences are what matter.

Ratio is an exclusively cognitive magnitude, completely devoid of emotional content.

Second Law: Justice Evaluation

Humans evaluate the justice or injustice of their natural endowments and social attributes and possessions by means of an implicit operation of the emotions and sentiments that can be formally represented as the logarithm of the Comparison Ratio. A magnitude of zero denotes a condition of perfect justice; a negative magnitude denotes unjust underreward; and a positive magnitude denotes unjust overreward.

Third Law: Justice Evaluation of Several Goods

At times, humans simultaneously (and, of course, instantaneously) regard their holdings of more than one good. At such times, the magnitude of the justice evaluation is equal to the arithmetic mean of the single-good justice evaluations. This relation may be expressed in several equivalent forms, such as the logarithm of the geometric mean of the Comparison Ratios.

◆

Notice that the general theory regards as exogenous the two sets of factors that produce the Actual condition and the Just condition (which in turn must be known before a justice evaluation can be predicted)—regards as exogenous, that is, the actual distributions of Goods and the individual's choice of Goods, Comparison Aggregates, and Just terms.[5] How and why some goods rather than others are chosen at particular moments, some Comparison Aggregates rather than others, some notions of justice rather than others, how and why humans change their minds (going from one justice evaluation to another, to another), how and why social goods come to be distributed in particular ways—these are questions about which the general theory is silent. Later in this paper we shall make some preliminary conjectures but, for now, the history of each justice evaluation lies outside our field of interest. What matters for now is what happens once a human experiences a particular magnitude of the sentiment of justice.

C. The Theory's Strategy for the Explanation of Social Phenomena

It is neither unreasonable nor novel to suggest that the sense of justice is a crucial determinant of much in the human condition. Whether one feels justly or unjustly treated, unjustly overrewarded or unjustly underrewarded—these are primordial sentiments; and to suggest that behaviors (as well as other sentiments) depend on them is merely to echo twenty-five hundred years of reflection on the human experience.

In social matters, the principal voices of Western literature grant to justice an unusual primacy. Justice, wrote Aristotle, is "the bond of men in states," and, more than bond, it is the sine qua non of friendship. Without scrupulous attention to distributive justice, wrote Cervantes, not even a band of thieves could live together.

We now suggest a simple systematization of our inherited view. Whenever individuals come together, aware of each other and of the aggregate they form, that Social Aggregate, at that point in time, may be represented by the frequency distribution of the instantaneous justice evaluations experienced by the members; and on the parameters of that frequency distribution depend many social variables of interest. Moreover, at that moment in time, the Social Aggregate *is* the Comparison Aggregate. Since, by definition, the members of the Social Aggregate are aware of the SA, it follows that any justice evaluations experienced by an individual qua member of the Social Aggregate will have the SA as Comparison Aggregate.

This means that in the general theory, the dynamic in social life flows from factors both internal and external to the individual, both inside and outside his/her control. The internal factors include the free selection of goods of value and of what the individual considers just, for him/herself, as well as the innate constraint in the mathematical manner in which he/she appraises the Actual condition and the Just term. The major external factors are the outcomes of the natural and social lotteries, over which the individual may have little or no control. All of these factors combine to produce a distribution of justice evaluations that may assume an infinity of shapes, locations, and scales.

---

[5] By leaving exogenous the selection of the Just term, this theory can accommodate both Homans' (1974) and Berger et al.'s (1972) conceptions of the sources of justice—that is, both existential and utopian notions of justice.

This collection of justice sentiments, which we use to represent the Social Aggregate, may (as may any observed distribution) be arranged into an array, and notice taken of its many parameters, such as the arithmetic mean, the lower extreme value, the Gini's mean difference, etc. These distributional parameters constitute the independent variables suggested by the theory for use in propositions explanatory of social phenomena. The theory thus affords an enormous number of possible explanatory terms or sets of terms.

Now, social phenomena are of two types: aspects of groups that are, first, merely aggregations of individual-level phenomena and, second, specifically social phenomena. The first type includes summary measures of any phenomenon observed at the level of the individual; for example, if the theory successfully explains the individual's propensity to criminal activity, then the aggregate crime rate should be a function of the mean propensity to criminal activity. The second type includes variables that are not observed in individuals, properly speaking, but only in aggregates—such phenomena as a group's propensity to dissolution and a group's propensity to violent revolutionary conflict. Both types of social phenomena, we suggest, may be explained and predicted by parameters of the observed distribution of instantaneous justice evaluations. Thus, we are suggesting that interpersonal relations, within a Social Aggregate, may be regarded as basically a meeting of justice sentiments.

As for the temporal dynamic in social life, we propose that it arises from changes in the Social Aggregate's frequency distribution of justice evaluations. This means that whenever individuals select new Goods to value or acquire new notions of Justice or form new Social Aggregates, or whenever the actual distribution of the Good of value changes, the particular configuration of justice sentiments undergoes a corresponding change—as do all parameters of interest and whatever social phenomena vary with them. Social change, then, can be understood as changes in the justice distribution.

D. Some Hypotheses

We now suggest some hypotheses for the relations between social dependent variables and the independent variables produced by the theory.[6] We emphasize here the preliminary nature of these hypotheses. Some may not survive systematic literature review and others may not survive empirical test; and the surviving hypotheses depend totally on empirical research for specification of their functional form and for parameter estimation. The propositions that follow both illustrate the formal structure of hypotheses that one can generate from the theory and suggest some substantive relations:

1. For all Social Aggregates, the propensity to dissolution—represented by the positive segment of the real-number line, with zero the point of perfect stability (i.e., absence of a propensity to dissolution)—varies directly with the Gini's mean difference of the distribution of justice evaluation scores. When the aggregate of interest is a political unit, the propensity to dissolution may be regarded as a measure of political instability. We consider that such propensity to dissolution, or instability, depends critically and equally on all pairwise relations in the aggregate, a notion precisely captured by the Gini's mean difference.

---

[6] We follow Toulmin's (1953:77–85) view of the hierarchical structure of a theory. Thus, some of the terms used in the hypotheses (for example, "lower extreme value of the distribution of justice evaluations in a Social Aggregate") "depend for their very *meaning*" on the set of Principles and Laws in the theory. The hypotheses and the Laws cannot be logically deduced from one another; rather, they are linked by terms which appear in both. The logical connection between the hypotheses and the Laws is that such terms as "lower extreme value of the distribution of justice evaluations in a Social Aggregate" can be introduced only by reference to the Law of Justice Evaluation. Moreover, the general theory of distributive justice meets the criterion of open-endedness, for it leaves to empirical discovery the exact relations between the terms it produces and other empirical terms.

2. For all Social Aggregates, the degree of concord or discord is equal to the arithmetic mean of the distribution of justice evaluations; at the societal level, this may be regarded as a measure of social content or discontent. This measure gives equal weight to the justice sentiments of all members of the SA. It may take on either a positive or a negative value.

3. The Social Aggregate's propensity to violent revolutionary conflict varies directly with the absolute magnitude of the lower extreme value of the distribution of justice evaluations. Once cleavage occurs, splitting the Social Aggregate into two warring segments, the intensity of the revolutionary violence varies directly with the arithmetic mean of the better-off segment's justice evaluations (i.e., with the higher of the two segments' arithmetic means). Thus, we regard injustice of the underreward sort (i.e., relative deprivation) as the main determinant of the propensity to revolution and injustice of the overreward sort (i.e., relative excess) as the main determinant of the intensity of violent revolutionary conflict.

4. Crime occurs in a Social Aggregate only when the SA contains both negative and positive justice evaluation scores (i.e., both underrewarded and overrewarded persons) and when the absolute magnitude of the lower extreme value is greater than the upper extreme value of the distribution. In such case, the crime rate varies directly with the proportion found in that left-most segment whose upper end-point is of identical absolute magnitude as the overall distribution's upper extreme value. We term such a segment a Distressed segment.

5. The mean seriousness of all crimes varies directly with the absolute magnitude of the mean of the Distressed segment.

6. The mean seriousness of crimes against persons varies directly with the absolute distance between the overall mean and the mean of the Distressed segment.

7. The rate of mental illness varies directly with the proportion of negative justice evaluation scores—but excluding the Distressed segment, if any.

8. The mean severity of mental illness varies directly with the absolute magnitude of the mean of the unjustly underrewarded segment—again excluding the Distressed segment, if any.

9. For all Social Aggregates, the rate of emigration varies with the arithmetic mean of the individual members' propensity to emigrate, where propensity to emigrate is specified as the principal value of the arc secant function of the justice evaluation for justice evaluations ≤ -1 or $\geq +1$ and as zero elsewhere. This formulation permits separate measurement of emigration "from the bottom" and emigration "from the top," a feature useful in the study of not only residential migration but also other instances of leaving a Social Aggregate, such as dropping out and transferring out of school.

◆

Now, unless we directly ascertain the Actual term and the Just term for each individual in the Social Aggregate, the general theory cannot predict the distribution of justice evaluations and, hence, cannot predict the values of any of the distributional parameters which we use as independent variables in the hypotheses. To say that the selection—of Goods to value, of Social Aggregates to form, and of notions of justice—is exogenous is to assert that there is no *general* relation between the objective distributions of the natural and social goods and the individual and social behaviors which this theory seeks to explain. Nevertheless, in Part II, we propose two restrictions to the general theory which permit us to predict the distribution of justice evaluations and all its parameters solely from the distribution(s) of the good(s) of value.

II. MATHEMATIZATION AND THEORETICAL DEVELOPMENT

We have seen that the distribution of justice evaluations produced by the general theory may assume an infinity of shapes, scales, and locations. We now, first, introduce two restrictions (to the general theory) which make possible prediction of the distribution of justice evaluations from knowledge of the distribution of the good of value; second, we present the basic formulas; third, we apply the theory to Social Aggregates; and, finally, we conclude with a note on testing the theory.

A. Two Simplifying Restrictions: The Primitive Alternatives

We now introduce two restrictions which limit the individual's freedom in the selection of goods of value and of Just terms and which, together, produce a particular empirical realization of the theory which we term the Primitive model. Although these restrictions are, in fact, alternatives in the individual's selections, they are so powerful and so universal and so often chosen that we regard them as "default" alternatives and call them the Primitive alternatives. Both alternatives are present to the individual and, yet, are expressions of the human's social nature. And, as we shall see, use of the two Primitive restrictions permits a priori generation of expected distributions of justice evaluations, thus simplifying the mathematization and the task of testing the theory.

1. The just condition: "justice is equality."

The Primitive alternative in the choice of the Just term is the condition of equality. We suggest that, within Social Aggregates, when humans consider goods, when humans reflect on their attributes and their possessions, their universal longing is for equality.

The earliest expression of this identity known to us appears as words of Socrates in the *Gorgias;* but it recurs frequently in Aristotle (e.g., in the *Nicomachean Ethics,* Book 8), in the Patristic literature, in Vives, and in Cervantes. Variants of this identity may be found in Bentham [1802] 1950:104) and in Hume [1777] 1965:194); the contemporary economist E. S. Phelps (1973:27) notes that most thinkers on distributive justice agree that the only just division of a fixed pie is an equal one. Finally, we recall the observations of Homans (1967:64–7) that "justice is what men expect" and that "the sense of injustice is invariably grounded on a defeat of expectations, and expectations in the long run are always grounded on what actually happens" and of Berger et al. (1972:133) that the just amount of a goal-object is that amount which is "typically allocated."

Quantification of the Just term is straightforward: the equal level or amount of a good is the arithmetic mean of the good's distribution. Notice how exquisitely both Homans and Berger and his associates intuited this fundamental relation: the mathematical expectation of a distribution is equal to the arithmetic mean; and the typical value of a distribution may be represented by the arithmetic mean.

Now, we consider that this longing for equality is rigidly confined to the Social Aggregate. This means that psychological "membership" in a Social Aggregate structures what individuals come to regard as just (see William James, [1891] 1952:887).

2. Consensus on the Goods of value in a Social Aggregate.

The second Primitive alternative suggests that all members of a Social Aggregate value the same good or goods; that is, Social Aggregates in the Primitive model are characterized by consensus on the goods of value. This restriction limits the choice of value for members of a Social Aggregate during moments of conscious membership in the Social Aggregate.

This restriction is somewhat difficult to discuss, and perhaps expresses well the tensions and ironies of the human condition. The restriction is a feature of Social Aggregates. It arises out of a social dynamic, and yet is freely accepted by the members of the Social Aggregate. Put differently, there is a mysterious something about Social Aggregates that generates a prompting, an enticement, to consensus both generally as well as specifically on the goods of value.

That persons so often accede to this enticement to consensus is perhaps the empirical reason why Augustine chose to include consensus in his definition of the term, "people." For Augustine ([413–426]

1952, *City of God,* Book 19, chap. 24), "a people is an assemblage of reasonable beings bound together by a common agreement as to the objects of their love."

Thus, while Nisbet's definition of a Social Aggregate is wonderfully apt for the general theory, in the Primitive model we invoke Augustine's narrower conception.

Now, consensus in general refers to many things, including beliefs, attitudes, moral demands. In the present theory, however, we notice consensus about only the goods of value. That is, we restrict attention to those goods about whose distribution humans experience justice evaluations. As we shall see, while consensus in general may be a fine thing, consensus about the goods of value has mixed consequences.

B. Basic Formulas at the Level of the Individual

An important feature of the present work is that much of what we have said in words can be economically represented in the language of mathematics. In this section, we present the major formulas for the terms of the theory at the level of the individual. We assume the two Primitive restrictions. All magnitudes are instantaneous.

1. The case of quality-goods.

Consider the distribution of a given quality-good (any quality-good—such as beauty, honor, or intelligence) in a Social Aggregate. We assume that the good's distribution is continuous; this assumption ensures that the probability of tied ranks is zero. Next, we generate the set of discrete rank-order statistics (ROS), arranged in ascending order of magnitude. This set is the set of integers from 1 to the size N of the Social Aggregate. Finally, we convert the rank-order statistics into percentile ranks (see Snedecor and Cochran, 1972:123–5), forming a new, continuous Rectangular distribution. The formula for obtaining the percentile rank is

$$P_i = \frac{\text{ROS}_i\,(100)}{N + 1}\,. \qquad (2)$$

The percentile rank is, of course, the Actual Rank. Now recall that the Just Rank in the Primitive model is 50, which is the arithmetic mean of the unit Rectangular (expressed as a percentile). Thus, the Primitive justice evaluation is given by

$$\begin{matrix}\text{justice}\\ \text{evaluation}_i\end{matrix} = \log_a \frac{\text{Actual Rank}_i}{50}\,, \qquad (3)$$

where a represents the logarithmic base implicitly used by each individual, a quantity which we conjecture may be the individual's signature constant. The formula above may be restated in the following more compact form:[7]

$$\begin{matrix}\text{justice}\\ \text{evaluation}_i\end{matrix} = \log_a \frac{2\,\text{ROS}_i}{N + 1}\,. \qquad (4)$$

For k quality-goods considered simultaneously, the formula is

$$\begin{matrix}\text{multi-good}\\ \text{justice}\\ \text{evaluation}_i\end{matrix} = \log_a \left(\frac{2}{N + 1} \sqrt[k]{\prod_{j=1}^{k} \text{ROS}_{ij}} \right). \qquad (5)$$

2. The case of quantity-goods.

Consider the distribution of a given quantity-good (any quantity-good, such as wealth, earnings, income, land, or livestock) in a Social Aggregate. The quantity-good is measured in its own units. The order statistics, arranged in ascending order of magnitude, are represented by x_1, x_2, x_3, . . ., x_N, where N is the size of the Social Aggregate. The Just Amount in the Primitive model is the arithmetic mean of the goods's distribution, denoted by $\bar{x}$. Thus, the Primitive justice evaluation experienced by the i^{th} individual is given by

$$\begin{matrix}\text{justice}\\ \text{evaluation}_i\end{matrix} = \log_a (x_i/\bar{x})\,, \qquad (6)$$

where a is the individual's log base.

---

[7] A mathematically equivalent procedure for calculating the Primitive justice evaluation is as follows: Let Actual Rank be defined as the rank-order statistic; let Just Rank be defined as the arithmetic mean of the distribution of rank-order statistics, or (N+1)/2. Both procedures start out using a Discrete Uniform distribution and lead to a Continuous Uniform.

For m quantity-goods considered simultaneously, the formula for the justice evaluation experienced by the i$^{\text{th}}$ individual is given by

$$\begin{matrix}\text{multi-good}\\ \text{justice}\\ \text{evaluation}_1\end{matrix} = \log_a \sqrt[m]{\prod_{l=1}^{m} (x_{1l}/\bar{x}_l)}. \qquad (7)$$

3. Simultaneous consideration of quality-goods and quantity-goods.

The multi-good justice evaluation experienced by the i$^{\text{th}}$ individual about his/her level(s) and amount(s) of k quality-goods and m quantity-goods is given by

$$\begin{matrix}\text{multi-good}\\ \text{justice}\\ \text{evaluation}_1\end{matrix} =$$

$$\log_a\left\{ \sqrt[(k+m)]{\left(\frac{2}{N+1}\right)^k \left(\prod_{j=1}^{k} \text{ROS}_{1j}\right)} \cdot \sqrt[(k+m)]{\left(\prod_{l=1}^{m} (x_{1l}/\bar{x}_l)\right)} \right\}. \qquad (8)$$

4. Conversion of self-reported justice evaluations to the natural logarithmic scale.

While the experience of a given magnitude of the justice evaluation is the same across persons, individuals may vary in their style of description, some given to understatement, others to hyperbole. We represent this reporting style by the logarithmic base a used in the formula for the justice evaluation. Since the real-number line is infinitely dense, we conjecture that each individual may have a unique style of description, implicitly using a unique log base a. This log base a may be regarded as the individual's signature constant.

In order to render such self-reported justice evaluations comparable across persons, it is necessary to convert them into a uniform scale. We use the natural logarithmic scale for this purpose. The actual conversion process is in two steps. First, we must ascertain the log base a used by the individual; and, second, we must perform a change-of-base.

To find the individual's base a, we ascertain the Actual and the Just terms for a reported justice evaluation (denoted by^) and solve as follows:

$$a = \left(\frac{\text{Actual Term}}{\text{Just Term}}\right)^{1/\text{justice } \hat{\text{e}}\text{valuation}}. \qquad (9)$$

Next, we use the change-of-base theorem to convert the individual's self-reported scores to justice evaluations on the natural log scale:

$$\begin{matrix}\text{justice}\\ \text{evaluation}\end{matrix} = \frac{(\text{justice } \hat{\text{e}}\text{valuation})}{\log_a e}, \qquad (10)$$

where e is the base of the natural logarithms. At this point, a consequence of the change-of-base theorem becomes extremely useful, and that is:

$$\log_a \epsilon = 1/(\ln a). \qquad (11)$$

Hence, the simplest method of conversion is given by:

$$\begin{matrix}\text{justice}\\ \text{evaluation}\end{matrix} = (\text{justice } \hat{\text{e}}\text{valuation})\,(\ln a)\,. \qquad (12)$$

In this way, the self-reported justice evaluations are converted into a common scale and, hence, usable for interpersonal comparison as well as in the frequency distributions that we use to represent Social Aggregates.

C. Application of the Theory to Social Aggregates and Social Phenomena

The Primitive model, by holding constant the good(s) of value to the members of the Social Aggregate and the condition regarded by them as just, enables us to move swiftly from knowledge about the distribution(s) of the good(s) of value to the distribution of justice evaluations. Moreover, if the good of value is a quality-good, it is not even necessary to ascertain the Actual Rank of individual members of the Social Aggregate, for we already have all the information required to describe the distribution of justice evaluations and all its parameters.

There are two ways of approaching the task of representing Social Aggregates by their respective distributions of justice evaluations. The first uses the methods of descriptive statistics to answer the a posteriori questions: If the good of value has such-and-such an observed frequency distribution, then, given the Primitive restrictions, what does the distribution of justice evaluations look like? What are the observed values of the parameters of interest? This approach is particularly useful when studying Social Aggregates of small size N.

The second approach uses classical probability procedures to answer the a priori questions: If the distribution of the good of value has such-and-such density function, then (given the Primitive restrictions) what is the density function of the expected distribution of justice evaluations? What are the expected values of the parameters of interest?

1. Parameters of observed frequency distributions of justice evaluations.[8]

(a) The observed lower extreme value

Consider a Social Aggregate of size N; the members consensually value one good, either a quality-good or a quantity-good. The lower extreme value (LEV) of the distribution of justice evaluations is calculated as follows:

$$\text{lower extreme value} = \begin{cases} \ln \dfrac{2}{N+1}, & \text{quality-good} \\ \ln \dfrac{x_1}{\bar{x}}, & \text{quantity-good} \end{cases}, \quad (13)$$

where x_1 is the first order statistic of the quantity-good's observed frequency distribution and where $\bar{x}$ is its arithmetic mean.

The formulas for the lower extreme value of the distribution of justice evaluations underscore an implication of the theory: the size of the Social Aggregate always affects the experience of justice about quality-goods. The lower limit of the LEV, as N goes to infinity, is negative infinity. For quantity-goods, the lower limit of the LEV is also negative infinity, but the process is different; in this case the size of the LEV is a function of the ratio of the size of the smallest share of the good to the mean, and the lower limit goes to negative infinity as this ratio approaches zero from the right. Through its effect on the mean, N may also affect the LEV of the quantity-good's distribution.[9]

But whatever the process, whether due to the size of the Social Aggregate or to the size of the share, the formulas above mean that the sense of injustice of the underreward sort has no bounds. There is no limit to the enormity of the human experience of being unjustly underrewarded.

(b) The observed upper extreme value

Consider a Social Aggregate of size N; the members consensually value one good, either a quality-good or a quantity-good. The upper extreme value (UEV) of the distribution of justice evaluations—that is, the largest magnitude of unjust overreward—is calculated as follows:

$$\text{upper extreme value} = \begin{cases} \ln \dfrac{2N}{N+1}, & \text{quality-good} \\ \ln \dfrac{x_N}{\bar{x}}, & \text{quantity-good} \end{cases}, \quad (14)$$

where x_N is the N^{th} order statistic of the quantity-good's observed array.

The upper end of the distribution has a very striking feature. When the good of value is a quality-good, the upper limit of the upper extreme value is ln 2 (about .6931, rounded), a very rigid and modest limit to the experience of overreward. No such bound accompanies the experience of overreward about quantity-goods; in this case, the upper limit goes to positive infinity as the ratio of the size of the largest share to the mean goes to positive infinity.

These formulas have important empirical implications. For example, the most beautiful or most brilliant person in a Social Aggregate experiences a very modest magnitude of overreward. And whatever behavioral consequences are hypothesized to follow or accompany the large magnitudes of the sense of being overrewarded (such as guilt feelings or redress-ing behaviors) will be found only with respect to quantity-goods. Thus, for the case of social goods, the Primitive model predicts such behavioral consequences only when the good of interest is a material good, such as wealth or income, and not for such goods as honor or occupational prestige.

---

[8] Due to space limitations, we present formulas for only three of the parameters of observed distributions of justice evaluations.

[9] I am grateful to the anonymous referee for pointing this out.

(c) The observed arithmetic mean

Calculation of the arithmetic mean of the observed frequency distribution of justice evaluations renders visible a relation we regard as very exciting. Let us begin by deriving the arithmetic mean for the case of one good of value, either a quality-good or a quantity-good.

$$\text{arithmetic mean} = \begin{cases} \dfrac{\sum_{i=1}^{N} \ln\left(\dfrac{\left(\dfrac{100\,ROS_i}{N+1}\right)}{50}\right)}{N}, & \text{quality-good} \\[2ex] \dfrac{\sum_{i=1}^{N} \ln \dfrac{x_i}{\bar{x}}}{N}, & \text{quantity-good} \end{cases} \quad . \ (15)$$

The expressions above may be restated in their equivalent forms:

$$\text{arithmetic mean} = \begin{cases} \ln \dfrac{\sqrt[N]{\prod_{i=1}^{N}\left(\dfrac{100\,ROS_i}{N+1}\right)}}{50}, & \text{quality-good} \\[2ex] \ln \dfrac{\sqrt[N]{\prod_{i=1}^{N} x_i}}{\bar{x}}, & \text{quantity-good} \end{cases} \quad . \ (16)$$

Viewed in this way, it is immediately clear that the arithmetic mean of the distribution of observed justice evaluations in a Social Aggregate is the logarithm of the ratio of the geometric mean of the distribution of the good of value to the arithmetic mean of the good's distribution. That is,

$$\text{arithmetic mean} = \ln \frac{\text{Geometric Mean of the Good}}{\text{Arithmetic Mean of the Good}} \ . \quad (17)$$

Before turning to a discussion of this relation, we present a simple equivalent expression for the case of a quality-good, so simple that it makes an excellent computational formula:

$$\text{arithmetic mean} = \ln\left(\frac{2}{N+1}\sqrt[N]{N!}\right), \ \text{quality-good} \ , \quad (18)$$

where N! represents N-factorial. It can readily be shown that as the size N of the Social Aggregate increases, the arithmetic mean of the justice evaluations moves leftward, attaining progressively larger absolute values of negative magnitudes and approaching its limit of (ln2 − 1) or about −.3069. In the case of quantity-goods, there is no relation between N and the mean.

Returning now to the general formula for the arithmetic mean of the observed distribution of justice evaluations, let us look first at the ratio of the geometric mean to the arithmetic mean of the good's distribution. We regard this ratio as an interesting, if unorthodox, measure of relative dispersion in a distribution. It is unorthodox because measures of relative dispersion are usually formed by taking the ratio of a measure of absolute dispersion to a measure of location (e.g., the coefficient of variation) and not by taking the ratio of one to another measure of location. Nevertheless, the ratio has several interesting properties. First, since in all distributions of positive magnitudes except an Equal one the geometric mean is smaller than the arithmetic mean, the value of the ratio has fixed limits of zero and one (open at zero, closed at one). Second, the value of the ratio is independent of the units in which the good is measured. Third, the ratio is extremely easy to calculate. Finally, its most important feature may lie in its hypothesized relation to social discontent. If social discontent turns out to vary with the arithmetic mean of the justice distribution, then we may have hit upon a measure of inequality that is relevant to discontent, and we may have specified the theoretical relation:

$$\text{Social Discontent} = \ln \text{Inequality} \ . \quad (19)$$

2. *Expected distributions of justice evaluations.*

The expected distribution of justice evaluations in a Social Aggregate, given the Primitive restrictions, can be generated a priori—if we know the following three things: (1) What are the goods of value? (2) What is the probability density function of each? (3) And what are the intercorrelations among the goods? We now derive three of the simplest expected distributions and calculate the predicted values of the major parameters of interest. We have relied chiefly on three sources: Hoel (1971), Johnson and Kotz (1970a and 1970b), and Hastings and Peacock (1974).

(a) Generating expected distributions of justice evaluations

In this section, we look at three possible Social Aggregates, each having one good of value. In one Social Aggregate, the good of value is a quality-good, such as social honor or beauty or academic performance. In the other two Social Aggregates, the good of value is a quantity-good, such as any of a host of money variables (e.g., wealth, income, earnings, allowance) or land or livestock. Simply by knowing the distribution of the good of value, we can discover the distinctive representation of the Social Aggregate and predict its social facts. These three cases are offered not only as idealized representations but also as empirical possibilities.

The general method for generating expected distributions of justice evaluations is as follows: For single-good distributions, we take the actual distribution of the variable x (i.e., the good), and perform a change-of-variable in order to derive the distribution of the new variable y that is a function of the variable x, the function being the division of x by its own arithmetic mean (i.e., y is the Comparison Ratio). Next, we perform a second change-of-variable in order to derive the distribution of the new variable z that is a logarithmic function of y—that is, z is the justice evaluation.

For multi-good distributions, both change-of-variable and convolution techniques are used to obtain the distribution of multi-good justice evaluations.

All expected distributions are defined by their probability density function, denoted by f(x). Following the notation in Hastings and Peacock (1974), we use italicized small letters of the English alphabet to refer to the three basic parameters. These are:

> *a*—the location parameter. This parameter is the abscissa of a location point, usually the upper or lower or mid-point of the range.
> *b*—the scale parameter.
> *c*—the shape parameter.

The density functions for the distributions of justice evaluations are reported both in terms of their "own" parameters and as functions of the parameters of the good's distribution. In this way we can both quickly identify a given density as a member of a particular family of curves and make use of everything that is known about that family of curves and also see vividly how the characteristics of the distribution of the good of value affect the distribution of justice evaluations.

We do not in this paper formally report any of the multi-good densities we have obtained. However, notice that the many possible combinations of number of goods of value, of their intercorrelations, and of their densities make possible many distinct representations of Social Aggregates and hence help to produce the "infinite variety" of social life. We emphasize, again, our view that the multiform richness of social life may be of simple etiology and that the unifying principle may be the sense of justice.

(1) The case of one quality-good. Consider a Social Aggregate of very large size N tending to infinity. By the second Primitive restriction, all the members of the Social Aggregate value the same good. In this particular case, that one good is a quality-good. By the first Principle, the distribution of the Actual Ranks is a unit Rectangular whose loca-

tion parameter a equals zero and whose scale parameter b equals one. The density thus is given by:

$$f(x) = 1 \ , \ 0 < x < 1 \ . \qquad (20)$$

The graph of the probability density function for the unit Rectangular is shown on panel a. of Figure 1.

By the first Primitive restriction, the Just term for each member of the Social Aggregate is the good's arithmetic mean, the point of equality. The arithmetic mean of the unit Rectangular is .5. By a change-of-variable, we obtain the density function of the distribution of the members' Comparison Ratios. This new density also belongs to the Rectangular family:

$$g(y) = .5 \ , \ 0 < y < 2 \ . \qquad (21)$$

Finally, we perform a second change-of-variable in order to obtain the density of the justice evaluation variable in the Social Aggregate. That is, we obtain the density of the new variable that is a natural-logarithmic function of the Comparison Ratio variable. The new density is:

$$q(z) = e^{z}/2 \ , \ -\infty < z < \ln 2 \ . \qquad (22)$$

Upon inspection, we recognize this density as belonging to a negatively skewed family of Exponential distributions. The general formula, now using x to denote the variate, is given by:

$$f(x) = \frac{e^{(x-a)/b}}{b} \ , \ -\infty < x < a \ . \qquad (23)$$

In the present case the value of the scale parameter b equals one, and the value of the location parameter a equals ln 2. The graph of this probability density function that results from consensual valuation of one quality-good is shown on panel b. of Figure 1. (The graphs of the justice distributions shown on the b. panels of the three figures are drawn to the same scale.)

The location parameter a ($a = \ln 2$) has a very interesting interpretation. It is both the upper limit of the justice evaluation variable—that is, the greatest possible magnitude of unjust overreward, and the cologarithm of the Just term (which is .5). Thus, we can say that the Just term determines the upper limit of the sense of justice with respect to quality-goods as well as the location parameter of the distribution's density function.

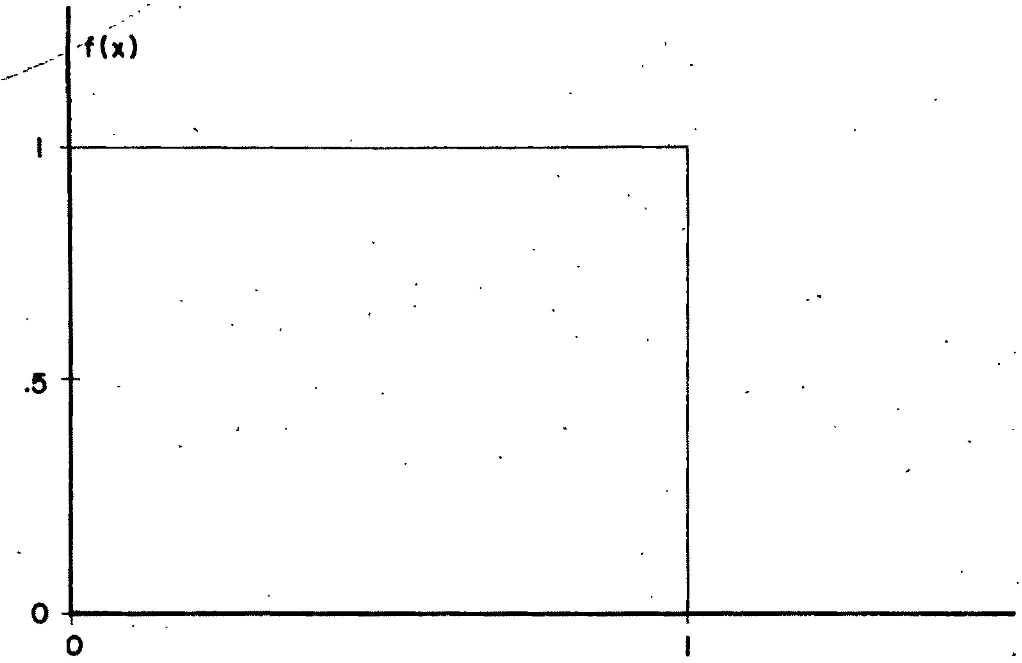
In section *2.(b)* below we shall look closely and precisely at the properties of this distribution. Here we merely note that, since in the Rectangular the arithmetic mean and the median are equal, we know that half of the members of the Social Aggregate experience unjust underreward while the other half feel unjustly overrewarded. We also know that the experience of injustice of the underreward sort ranges to negative infinity—that is, that the Social Aggregate has members who feel extremely unjustly underrewarded. Put differently, while the proportions in either condition of injustice are equal, their experience is vastly different. The intensity of the two segments' sentiments of justice differs greatly—just how greatly we shall see in section *2.(b)*.

(2) The case of a Pareto-distributed quantity-good. Consider a Social Aggregate of very large size N tending to infinity. By the second Primitive restriction all the members of the Social Aggregate value the same good. In this particular case, that one good is a quantity-good. Now the distribution of a quantity-good is regarded by this theory as exogenously given. Hence, its density function must be either empirically estimated or introduced by a priori restriction. In this section and the next, we imagine that the quantity-good of value is distributed as a Pareto and as a Lognormal variate, respectively, and inquire what may be the consequences of such distribution for the sentiment of justice experienced by the members of the Social Aggregate.

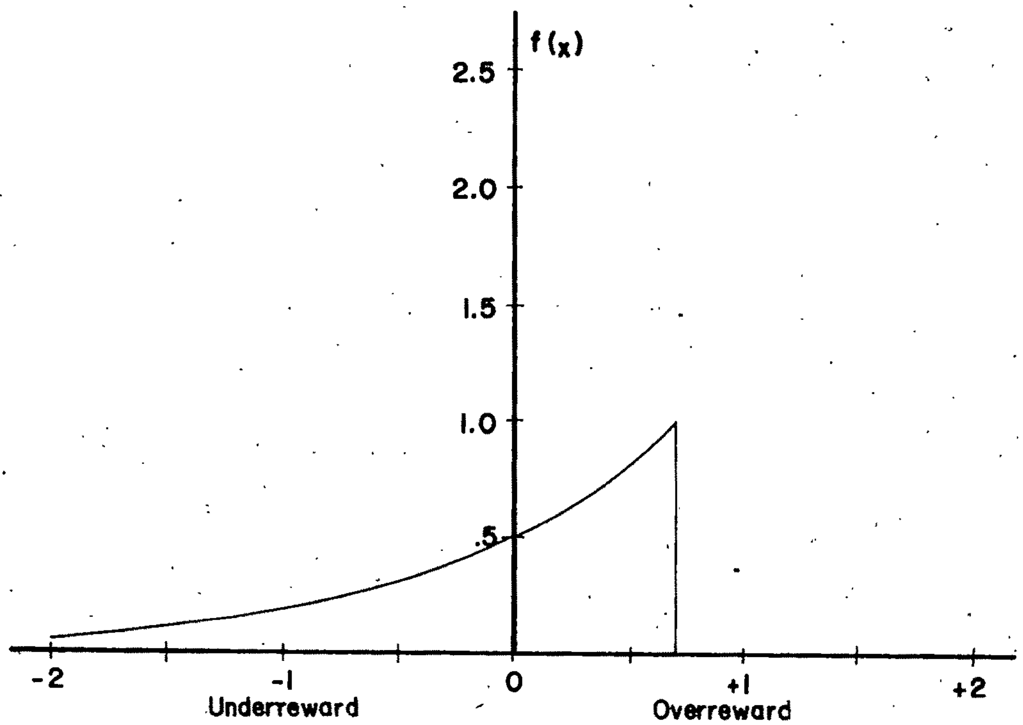
Suppose now that the quantity-good is Pareto-distributed.[10] The major features of the Pareto variate's probability density

---

[10] Many quantity-goods of value to diverse Social Aggregates may indeed be Pareto-distributed. Some examples are: family income in a welfare state; earnings within skill level, seniority, and firm; children's allowances within age cohort at a summer camp.



a. Unit Rectangular Density Function



b. Negatively Skewed Exponential Density Function

Figure 1. Distribution of Quality-Good and of Justice Evaluations

function are that it is everywhere decreasing, with a long right tail, and that the mode occurs at the lower limit. The Pareto family is often expressed in terms of a transformed variable, which is obtained by first dividing all observations by the lower extreme value. For example, if the lower extreme value of a given income distribution is $7,238.49, then all the income amounts are divided by that quantity—thereby producing a new distribution whose lower extreme value is unity. When expressed this way, the Pareto is a one-parameter family; that one parameter is a shape parameter known as Pareto's constant. Pareto's constant is considered a crude measure of inequality in the distribution (e.g., Cramer 1971:51–8), with inequality decreasing as Pareto's constant increases.

The density function of the transformed Pareto variate is given by:

$$f(x) = cx^{-c-1}\ , \quad 1 < x < +\infty\ . \tag{24}$$

Graphs of the density functions of three members of the Pareto family are shown on panel a. of Figure 2. They are drawn in terms of the untransformed variable (e.g., raw-income amounts). (The graphs of the quantity-good distributions shown on the a. panels of Figures 2 and 3 are drawn to the same scale; and each of the six curves has an arithmetic mean of 10.)

By the first Primitive restriction, the Just term for each member of the Social Aggregate is the good's arithmetic mean, the point of equality. Now Pareto's constant, or the shape parameter c, may assume any positive value. However, the arithmetic mean of the Pareto distribution is theoretically defined only when c is greater than one. Hence, we introduce the additional restriction that c must exceed unity. In such case, the arithmetic mean of the Pareto variate is equal to $(c/(c-1))$. By a change-of-variable, we obtain the density function of the distribution of the members' Comparison Ratios. This density is:

$$g(y) = cy^{-c-1}(c/(c-1))^{-c}\ , \qquad ((c-1)/c) < y < +\infty\ . \tag{25}$$

Finally, we perform a second change-of-variable in order to obtain the density of the justice evaluation variable in the Social Aggregate. The new density is:

$$q(z) = \frac{e^{-cz}(c-1)^c}{c^{c-1}}\ , \qquad \ln((c-1)/c) < z < +\infty\ . \tag{26}$$

Upon inspection, we recognize this density as belonging to a positively skewed family of Exponential distributions. The general formula, now using x to denote the variate and a and b to denote the Exponential's own location and scale parameters, is given by:

$$f(x) = \frac{e^{-(x-a)/b}}{b}\ , \quad a < x < +\infty\ . \tag{27}$$

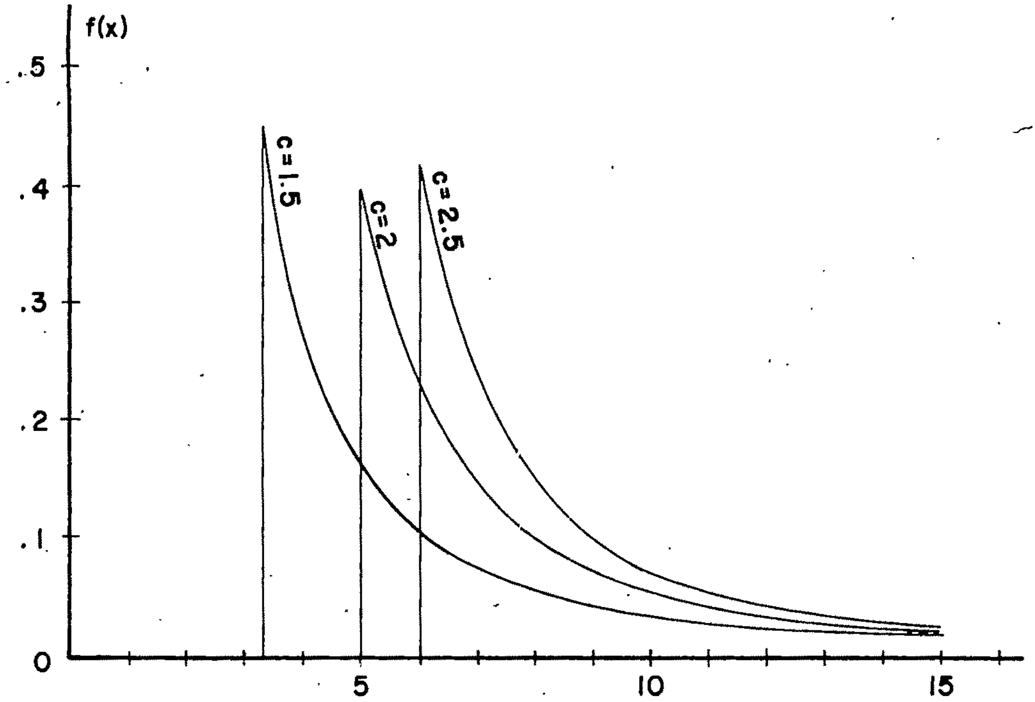
Graphs of the density functions of three members of this family are shown on panel b. of Figure 2.

Let us look now at the Exponential's two basic parameters and at their relations to the one parameter of the Pareto-distributed quantity-good. The Exponential's location parameter a is the lower limit of the Exponential; it is also the cologarithm of the Pareto variable's arithmetic mean. In other words, the Just term—the arithmetic mean of the Pareto distribution of the quantity-good—determines the location parameter of the distribution's density function (determines, that is, the lower limit of the sense of unjust underreward). And the Just term itself may be regarded as a function of Pareto's constant.

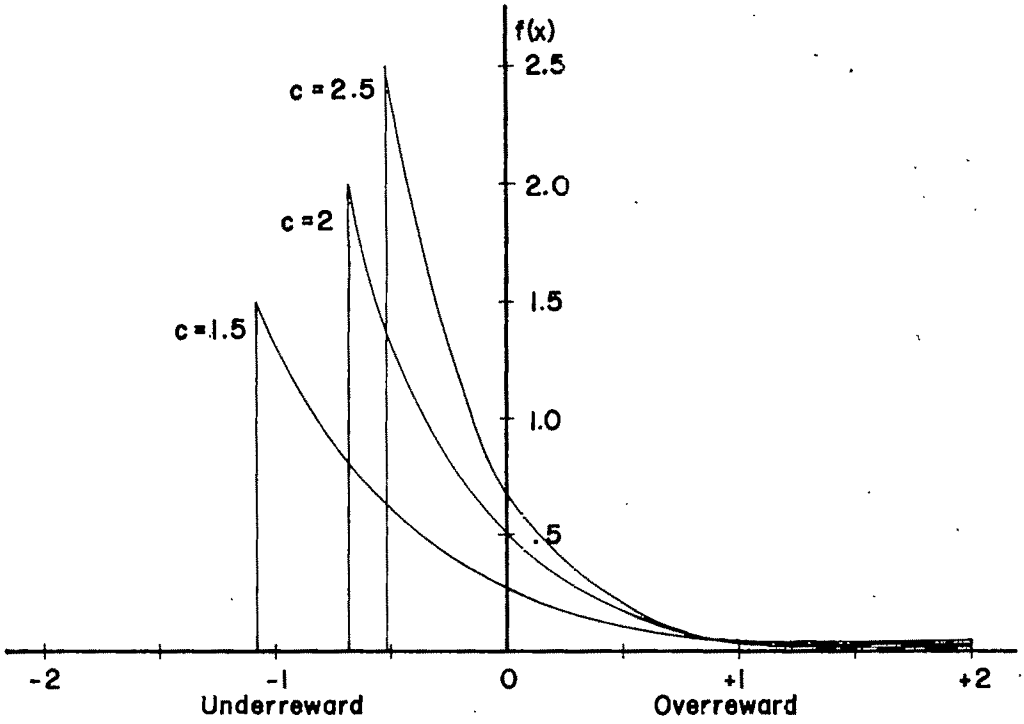
The Exponential's scale parameter b is also a function of Pareto's constant, being its reciprocal.

The Exponential's arithmetic mean we already know to be the logarithm of the ratio of the quantity-good's geometric mean to the quantity-good's arithmetic mean. Since both the geometric mean and the arithmetic mean are functions of Pareto's constant, we see clearly that the Exponential's arithmetic mean is also a function of Pareto's constant.

In section 2.*(b)* below we shall see precisely how these and other properties of



a. Pareto Density Functions



b. Positively Skewed Exponential Density Functions

Figure 2. Distributions of Pareto Quantity-Good and of Justice Evaluations

the Exponential family depend on various functions of Pareto's constant. At this point we merely say that, crudely, in one way or another, they *all* depend on the inequality in the distribution of the quantity-good.

Notice that while choice of one quality-good by the members of a Social Aggregate leads directly to one (and only one) distribution of justice evaluations—the negatively skewed Exponential described earlier—choice of one quantity-good may lead not only to different families of curves but also to different members of a family of curves. In the present case, the value of Pareto's constant may be said to determine the particular member of the Exponential family—that is, both the location and scale parameters of the positively skewed Exponential distribution of justice evaluations—that results from consensual valuation of one Pareto-distributed quantity-good.

The density function of this distribution shows that there is often a modest bound on the experience of unjust underreward when the quantity-good is Pareto-distributed. Very large absolute magnitudes, however, are to be found for the experience of overreward. But this family of curves is no panacea, for the proportion unjustly underrewarded is rather large.

This quantification renders unambiguous the meaning of the first Primitive restriction—the sense of justice responds to relative conditions. The absolute location of the quantity-good's distribution is totally irrelevant; only the inequality or dispersion in the distribution is of any import. This formulation points the way to design of strategies for reducing discontent, political instability, and the propensity to violent revolutionary conflict—and for doing so whether per capita income is increasing, decreasing, or remaining constant.

(3) The case of a Lognormally-distributed quantity-good. Consider a Social Aggregate of very large size N tending to infinity. By the second Primitive restriction, all the members of the Social Aggregate value the same good. In this case, that one good is a quantity-good and it is Lognormally distributed.

The Lognormal variate is a positively skewed, two-parameter family of curves with one important property: the distribution formed by the logarithms of the original observations belongs to the Normal family. The Lognormal has a range from zero to positive infinity. The two parameters are the scale parameter b which is the median of the distribution and the shape parameter c which is the standard deviation of the distribution of logged observations. The density function is given by:

$$f(x) = \frac{e^{-(\ln(x/b))^2/2c^2}}{xc\sqrt{2\pi}}, \; 0 < x < +\infty \,. \quad (28)$$

Graphs of the density functions of Lognormal curves are shown on panel a. of Figure 3.

By the first Primitive restriction, the Just term for each member of the Social Aggregate is the good's arithmetic mean, its point of equality. The mean is given by (b exp($c^2/2$)). By a change-of-variable, we obtain the density function of the distribution of the members' Comparison Ratios. The new density function is:

$$g(y) = \frac{e^{-((\ln y)+(c^2/2))^2/2c^2}}{yc\sqrt{2\pi}}, \quad 0 < y < +\infty \,. \quad (29)$$

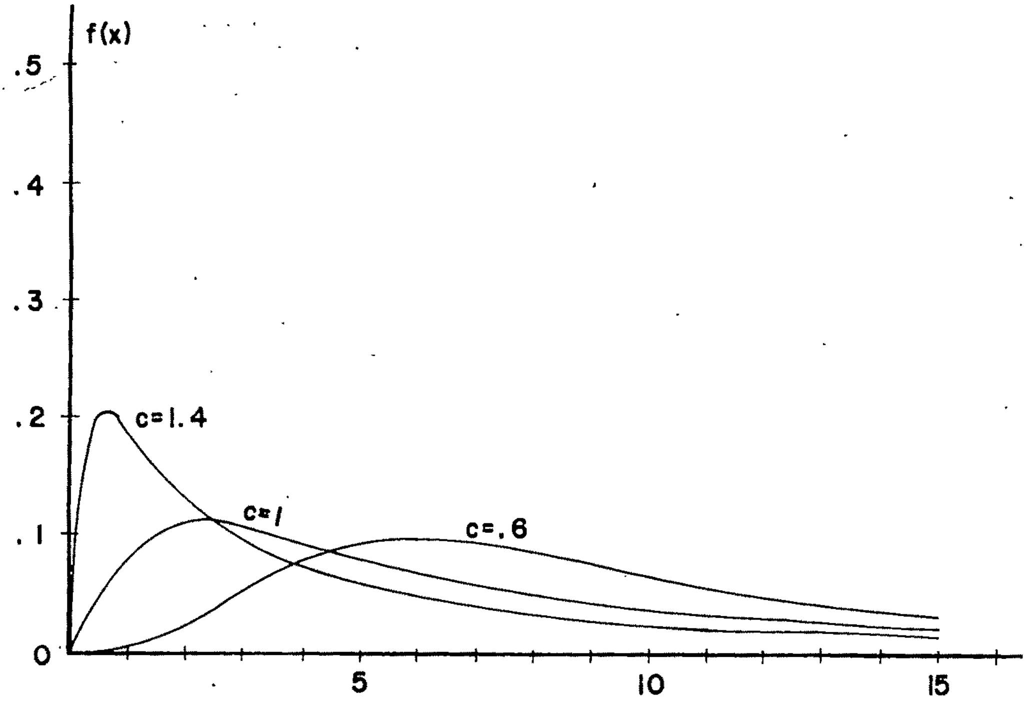
Notice that the Lognormal's scale parameter b is cancelled out at this step, so that the new density is solely a function of the Lognormal's shape parameter c.

Finally, we perform a second change-of-variable in order to obtain the density of the distribution of justice evaluations in the Social Aggregate:

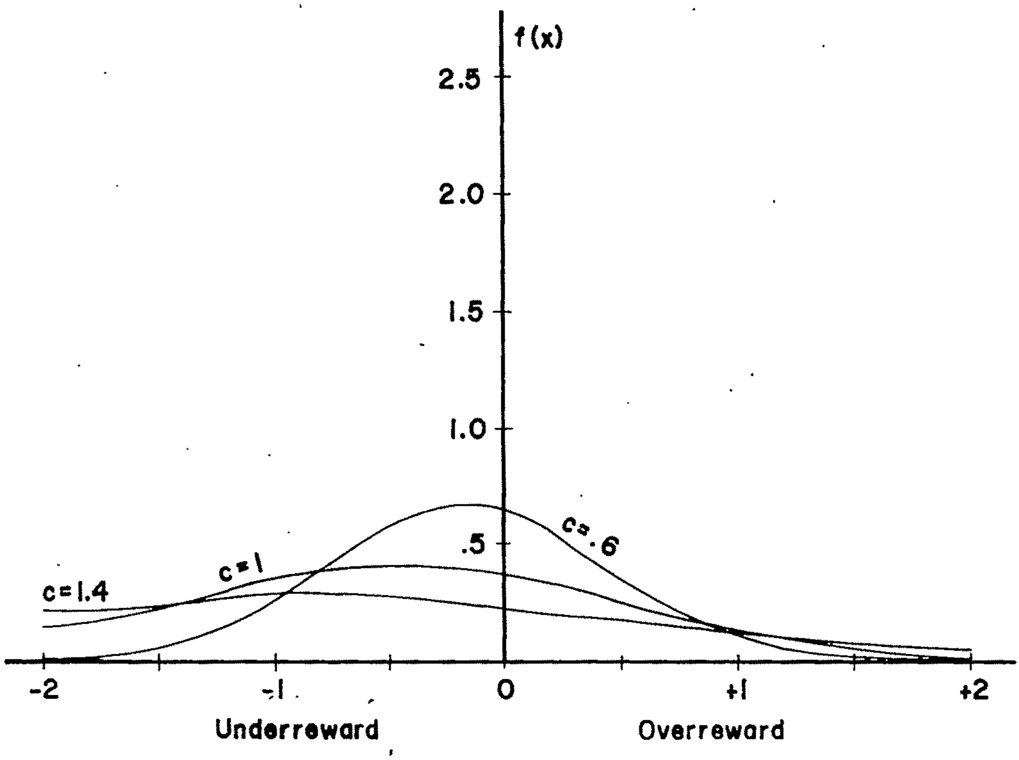
$$q(z) = \frac{e^{-(z+(c^2/2))^2/2c^2}}{c\sqrt{2\pi}}, \quad -\infty < z < +\infty \,. \quad (30)$$

This is, of course, a Normal density.

We now re-state it, using x to denote the Normal variate, a to denote the Normal's own location parameter, and b to denote the Normal's own scale parameter:



a. Lognormal Density Functions



b. Normal Density Functions

Figure 3. Distributions of Lognormal Quantity-Good and of Justice Evaluations

$$f(x) = \frac{e^{-(x-a)^2/2b^2}}{b\sqrt{2\pi}}, \quad -\infty < x < +\infty . \qquad (31)$$

In the Normal family the arithmetic mean is identical to the location parameter *a*, and the standard deviation is identical to the scale parameter *b*. Comparing the two expressions above, we see that the Normal's scale parameter *b* is identical to the Lognormal's shape parameter *c* and that the Normal's location parameter *a* is also a function of the Lognormal's shape parameter *c* (Normal's a = Lognormal's $-c^2/2$). Thus, we can re-state the density function again, this time expressing the new Normal in terms of one basic parameter:

$$f(x) = \frac{e^{-(x+(b^2/2))^2/2b^2}}{b\sqrt{2\pi}}, \quad -\infty < x < +\infty . \qquad (32)$$

Graphs of these Normal densities are shown on panel b. of Figure 3.

Thus we see that the Lognormal's shape parameter *c* determines both the mean and the standard deviation of the Normal distribution of justice evaluations that results from consideration of one Lognormally distributed quantity-good.

The Lognormal's shape parameter *c* may be regarded loosely as a measure of inequality and hence we may say that as inequality in the distribution of the quantity-good increases, the location of the distribution of justice evaluations moves leftward and inequality in justice sentiments increases as well.

These characteristics indicate that whenever the members of a Social Aggregate consensually value one Lognormally distributed quantity-good, the distribution of the sentiment of justice will be Normal with a negative mean and hence with more than half of the members experiencing unjust underreward. In the Normal, both tails go to infinity; thus, there are no limits to the experience of either extreme of injustice.

We pause to consider together the three curves we have produced. When all the members of a Social Aggregate consensually value one quality-good and accept equality as the Just term, "everything" is fully determined "inside" the theory. In such case, the distribution of Actual Ranks is Rectangular and the distribution of justice evaluations is a negatively skewed Exponential. But when the good of value is a quantity-good, then the theory—alone—cannot produce a distribution of justice sentiments; rather, "everything" depends on the actual distribution of the good.

We have considered only two families of curves as distributions of the one quantity-good. For these two, the Lognormal and the Pareto, we note that, though they behave differently in some respects, they have in common some important properties. If we hold constant the quantity-good's arithmetic mean (that is, the true arithmetic mean of the distribution of raw amounts), then we observe that: As inequality in the quantity-good's distribution decreases (with a decrease in inequality crudely indicated by an increase in Pareto's constant and by a decrease in the Lognormal's shape parameter *c*), the quantity-good distribution's median and mode move rightward toward the mean; and the proportion to the left of the mean decreases.

But of far greater importance is the effect of the inequality in the quantity-good's distribution on the distribution of justice evaluations. Regardless of the quantity-good's arithmetic mean, as inequality in the quantity-good's distribution decreases (again with a decrease in inequality crudely indicated by an increase in Pareto's constant and by a decrease in the Lognormal's shape parameter *c*), the distribution of justice evaluations moves rightward; the mean, median, and mode move toward zero; the proportion unjustly underrewarded decreases; the distribution contracts and grows taller, exhibiting a tendency toward a Dirac's Delta distribution, as defined by:[11]

$$\delta(x) = \begin{cases} 0 & , x \neq 0 \\ +\infty & , x = 0 \end{cases} . \qquad (33)$$

---

[11] Since Dirac's Delta function has the property that the integral is equal to +1, that is,

$$\int_{-\infty}^{\infty} \delta(x)\, dx = 1$$

p 17231

Thus, given consensual valuation of a quantity-good, the present theory clearly and unequivocally asserts the primacy of the degree of inequality in the quantity-good's distribution for determination of a host of social variables. The aggregate amount of the good is irrelevant; only the amount of inequality in its distribution is important. This vividly suggests that poorer societies can be socially better-off than richer ones, and specifies the condition under which this may be so.

(b) Evaluating the distributional parameters of interest

We have described the procedure for generating expected distributions and are now ready to evaluate their parameters. We shall continue working with the same distributions we generated in the preceding section.

Recall now that the parameters we are interested in include the overall arithmetic mean of the distribution of justice evaluations, the upper and lower limits, the Gini's mean difference, the proportions in various segments, and the arithmetic means of the various segments. (Although these are the only terms we evaluate in this paper, we note that other aspects of the distribution of justice evaluations may operate as independent variables in the specification of social phenomena.)

For each of these terms, we first provide the general, distribution-independent expression. Now, when the good is one quality-good, each term has one precise value; but when the good is one quantity-good, each term has a distinctive analytic solution (depending on the quantity-good's distribution), as well as a range of possible numerical values (depending on the degree of inequality in the quantity-good's distribution). Hence, for each term, we also provide the analytic solutions corresponding to the two families of curves we have obtained, as well as their theoretical limits as inequality varies. Finally, we provide numerical estimates for each term for seven curves, the negatively skewed Exponential that arises from consensual valuation of one quality-good, three positively skewed Exponentials, each arising from consensual valuation of one Pareto-distributed good of distinct Pareto's constant *c*, and three Normals, each arising from consensual valuation of one Lognormally distributed good of distinct shape parameter *c*.

All terms are obtained by evaluation of the appropriate integral. In some cases, the analytic solutions are well known (for example, the Gini's mean difference of the Normal curve). In other cases, we obtained the analytic solutions ourselves (for example, the arithmetic mean of the underrewarded segment of the positively skewed Exponential). A few of the terms have no analytic solution (notably some of the area terms of the Normal curve) so, for these, we used tabled values to approximate numerical solutions.

Table 1 reports most of the terms we have obtained for the curves discussed in this paper. Because space limitations preclude verbal description of all terms for all the curves, we will describe in words only the terms belonging to the positively skewed Exponentials that result from consensual valuation of one Pareto-distributed quantity-good. Of course, Table 1 provides all information for all the terms of all seven curves discussed in this paper.

◆

Here now is our summary description of aspects of the positively skewed Exponential family of distributions of justice evaluations:

(1) the lower limit—The lower limit of the positively skewed Exponential is equal to its location parameter *a*. We restricted Pareto's constant to values greater than unity and showed that the Exponential's location parameter *a* is an increasing function of the Pareto's shape parameter *c*. The lower limit of the distribution of justice evaluations, thus, is a function of *c*,

$$\text{lower limit} = \ln\frac{c-1}{c}. \qquad (34)$$

(see Zeldovich, 1973:423–5), and since the value of the function is always greater than or equal to zero, it satisfies the requirements for a probability density function, and we thus use it as a probability distribution. It is a perfect mathematical representation of an Equal distribution and (in this context) of a Social Aggregate all of whose members experience perfect justice.

Table 1. Principal Parameters of Some Distributions of Justice Evaluations

	Lower Limit	Arithmetic Mean	Gini's Mean Difference	Percent in Underrewarded Segment	Mean of Underrewarded Segment	Percent in Overrewarded Segment	Mean of Overrewarded Segment	Upper Limit
Distribution-Independent Expression		$_{-\infty}\int^{\infty} x\ f(x)\ dx$	$\int\int \lvert x_1 - x_2 \rvert f(x_1) f(x_2) dx_1 dx_2$	$F(0) = {}_{-\infty}\int^{0} f(x)dx$	$\frac{_{-\infty}\int^{0} x\ f(x)\ dx}{F(0)}$	$S(0) = {}_{0}\int^{\infty} f(x)\ dx$	$\frac{_{0}\int^{\infty} x\ f(x)\ dx}{S(0)}$

Note to Parts B. and C.:

By expressing the parameters of the distribution of justice evaluations as functions of the quantity-good's distribution, we are able to see the effects of inequality in the quantity-good's distribution. Notice that in the Pareto family of curves inequality increases as the value of Pareto's constant grows smaller, while in the Lognormal family inequality increases as the value of the shape parameter c grows larger.

The limits of *a* (that is, of the lower limit) are $-\infty$ as Pareto's constant approaches 1 from the right and zero as Pareto's constant goes to positive infinity. This means that, whenever the quantity-good is Pareto-distributed, the lower limit of the distribution of justice evaluations will be a negative quantity. (Of course, we already knew this, since, in the prior section *1.(a)*, we showed that the lower limit of the distribution of justice evaluations resulting from consensual valuation of an unequally distributed good would always be negative.) Turning now to individual members of this family, when Pareto's constant is 1.5, the lower limit is about −1.0986; when *c* is 2, the lower limit is about −.6931; and when *c* is 2.5, the lower limit is about −.5108.

(2) the upper limit—The upper limit of this family, like that of the underlying Pareto family, tends to infinity. However, its limit, as Pareto's constant goes to infinity, approaches zero from the right.

(3) the arithmetic mean—The arithmetic mean of the family of positively skewed Exponentials is given by $(a+b)$; it is thus a function of the Exponential's two basic parameters. However, recall that both the Exponential's basic parameters are functions of Pareto's constant, so that we may express the arithmetic mean as a function of the shape parameter *c* of the underlying Pareto variate. Thus, the Exponential's arithmetic mean is an increasing function of Pareto's constant, the formula given by

$$\text{arithmetic mean} = \ln\frac{c-1}{c} + \frac{1}{c}. \quad (35)$$

The limits of the arithmetic mean are negative infinity, as Pareto's constant approaches 1 from the right, and zero, as *c* goes to positive infinity. Notice that we could have arrived at this same result by using the function we obtained in section *1.(c)*—namely, the arithmetic mean of the distribution of justice evaluations is the logarithm of the ratio of the good's geometric mean to the good's arithmetic mean. In the Pareto variate, the geometric mean is the exponential function of the reciprocal function of *c* (that is, exp 1/c), and the arithmetic mean is $c/(c-1)$, so that the log of the ratio is the formula given above. Some values of the arithmetic mean are as follows: When Pareto's constant is 1.5, the arithmetic mean is about −.4319; when Pareto's constant is 2, the arithmetic mean is about −.1931; and, when Pareto's constant is 2.5, the arithmetic mean is about −.1108.

(4) the Gini's mean difference—The analytic formula for the Gini's mean difference of the distribution of justice evaluations is very simple for, in this case, the Gini's mean difference is an identity function of the Exponential's scale parameter *b*. Expressed in terms of Pareto's constant, the Gini's mean difference is the reciprocal function of Pareto's constant. Its limits are zero, as Pareto's constant goes to positive infinity, and one, as *c* approaches one from the right. Turning to some values of the Gini's mean difference—when Pareto's constant is 1.5, the Gini's mean difference is 2/3; when *c* is 2, the Gini's mean difference equals one-half; and, when *c* is 2.5, the Gini's mean difference is .4.

(5) the proportion underrewarded—The proportion underrewarded is the distribution function F(x) evaluated at x=0, that is, F(0). In terms of the underlying Pareto variate, it is the distribution function evaluated at x = the arithmetic mean, that is, $F(c/(c-1))$. The equivalent formulas are $(1 - \exp(a/b))$, in terms of the Exponential's basic parameters, and $(1 - ((c-1)/c)^c)$, in terms of Pareto's constant. The proportion underrewarded is thus a decreasing function of Pareto's constant. Its limit as Pareto's constant goes to infinity is the quantity one minus the reciprocal function of *e* (the base of the natural logarithms), that is, $(1 - 1/e)$. As Pareto's constant approaches one from the right, its limit is unity. Thus, the proportion underrewarded can never be less than about 63.21%. When Pareto's constant is 1.5, the proportion underrewarded is about 80.75%; when Pareto's constant is 2, the proportion underrewarded is 75%; and when Pareto's constant is 2.5, the proportion underrewarded is about 72.11%.

(6) the arithmetic mean of the underrewarded segment—This term is obtained by setting the area in the underrewarded segment equal to unity and then solving

for the first moment about the origin. In terms of the Exponential's basic parameters, the formula is

$$\text{underrewarded mean} = \frac{a + b(1 - e^{a/b})}{1 - e^{a/b}}. \quad (36)$$

In terms of Pareto's constant, the arithmetic mean of the underrewarded segment is an increasing function, defined by

$$\text{underrewarded mean} = \frac{\ln\frac{c-1}{c} + \frac{1}{c}\left(1 - \left(\frac{c-1}{c}\right)^{c}\right)}{1 - \left(\frac{c-1}{c}\right)^{c}}. \quad (37)$$

Its limits are negative infinity, as Pareto's constant approaches one from the right, and zero, as Pareto's constant goes to positive infinity. Turning to some specific values, when Pareto's constant is 1.5, the mean of the underrewarded segment is about −.6938; when c is 2, the mean of the underrewarded segment is about −.4242; and when c is 2.5, the mean of the underrewarded segment is about −.3084.

(7) the proportion overrewarded—The proportion overrewarded is the survival function S(x), evaluated at x=0, that is, S(0). In terms of the underlying Pareto variate, this term is the survival function evaluated at x equal the arithmetic mean, that is, S(c/(c−1)). The equivalent formulas are (exp a/b), in terms of the Exponential's basic parameters, and $((c-1)/c)^c$, in terms of Pareto's constant. Thus, the proportion overrewarded is an increasing function of Pareto's constant. Its limits are zero, as c approaches one from the right, and (1/*e*), as c goes to positive infinity. Thus, the proportion overrewarded is never greater than about 36.79%. Some values are as follows: When Pareto's constant is 1.5, the proportion overrewarded is about 19.25%; when c is 2, the proportion overrewarded is 25%; and when c is 2.5, the proportion overrewarded is about 27.87%.

(8) the arithmetic mean of the overrewarded segment—This term is obtained by setting the area in the overrewarded segment equal to unity and then solving for the first moment about the origin. In this case, this term has a simple formula; it is an identity function of the Exponential's scale parameter *b*. Alternatively, it is the reciprocal function of Pareto's constant. It is, thus, a decreasing function of c. Notice that, in this case, the arithmetic mean of the overrewarded segment is identical to the Gini's mean difference. Like the Gini's mean difference, its limits are zero, as Pareto's constant approaches positive infinity, and one, as Pareto's constant goes to one from the right. Turning to specific values, when Pareto's constant is 1.5, the arithmetic mean of the overrewarded segment is equal to two-thirds; when c is 2, the mean is .5; and when c is 2.5, the mean is .4.

There are in addition to these eight parameters many others that may be important in specifications of dependent variables. In this paper we have mentioned what we call the Distressed segment. When we first obtained the Exponentials discussed in this paper (and a Gamma family of curves not discussed in this paper), we were struck by the possibility of a Distressed segment and a Charmed segment in the left and right tails of negatively skewed and positively skewed curves, respectively. We defined a Distressed segment as the segment bounded by the lower limit and the negative fractile whose absolute value equals the upper limit; and we defined a Charmed segment as the segment bounded by the upper limit and by the positive fractile that equals the absolute value of the lower limit. And we conjectured, among other things, that crime exists only when there is a Distressed segment and that the crime rate varies directly with the proportion in the Distressed segment.

We still find much intuitive appeal in that notion and intend to test it, but we are unsure about its correct extension to Normal curves. We suspect that there exists a general rule for defining Distressed segments, of which our rule based on the bounds is a special case. However, we have not yet found it. So we provisionally apply our rule to the Normal curves, but use observed upper and lower extreme values instead of upper and lower limits to define the Distressed segment.

The negatively skewed Exponential that results from consensual valuation of one quality-good has a Distressed segment containing 25% of the population. The positively skewed Exponentials that result from consensual valuation of one Pareto-distributed quantity-good have no Distressed segment; instead they have a Charmed segment whose size varies directly with Pareto's constant, growing to an upper limit of $(1/e^2)$, or about 13.53%. Thus, we are led to the conjecture that there is very little crime, if any, in a society in which the good of value is one Pareto-distributed quantity-good and that there is a considerable amount of crime in a society in which the good of value is one quality-good.

As for the Normal curves obtained from consensual valuation of one Lognormally distributed quantity-good, if we make the simplifying assumption that all justice evaluations lie within plus or minus four standard deviations of the mean, then we find Distressed segments of such size as .03% when b equals .6, .13% when b equals one, and .47% when b equals 1.4. These are tiny Distressed segments, suggesting crime rates in these societies of much lower magnitude than in quality-good societies.

The foregoing discussion of Distressed segments underscores our view that, evaluating the parameters of the various distributions of justice evaluations—delightful exercise though it be—is not an end in itself. We do it because we are intrigued by the hypothesized relations between these parameters and social phenomena in the real world.

Thus, in terms of the theory, the information provided in Table 1 has a very precise meaning. Each of the seven rows represents a distinct Social Aggregate, and each term in each row represents one aspect of that Social Aggregate. For example, the first row of Table 1 is saying: There may be a Social Aggregate such that all the members value one and the same good, and that good is a quality-good, such as athletic skill, intelligence, social honor, or physical attractiveness; in such a Social Aggregate, half the members feel unjustly underrewarded, and the justice sentiment of the "bottom" person in the hierarchy of the good tends to negative infinity.

Likewise, each column in Table 1 is a vector of magnitudes of a variable attribute of Social Aggregates. For example, look at the column of proportion underrewarded. The expected values of this variable, according to Table 1, lie in the half-open interval, (.5,1]. The seven Social Aggregates described in Table 1 report values ranging from 50% to about 80.75%. This means that, if the good of value is a quality-good or if the good of value is one quantity-good of either Pareto or Lognormal distribution, then the proportion underrewarded in the Social Aggregate cannot be less than half.[12]

◆

Having looked in some detail at two families of quantity-good distributions—the Pareto and the Lognormal—we are now ready to state more explicitly the relation between the parameters of the distribution of justice evaluations and the magnitude of inequality in the quantity-good's distribution.

To begin with, all the major parameters of the distribution of justice evaluations are functions of the shape parameter c of the quantity-good's distribution. But they are different functions. We have already noticed that each aspect of the distribution of justice evaluations depends in its own particular way on the shape parameter c of the good's distribution, and that this particular way is specific to the distributional family. And we have noticed that the shape parameter c behaves quite differently in different distributional families. These features produce some rather interesting relations which we now summarize:

(1) Within a family of curves, the major parameters of the distribution of justice

---

[12] Of course, whenever the median of the good's distribution lies to the right of the arithmetic mean, the proportion unjustly underrewarded will be less than half. I am currently working with families of negatively skewed Beta and Gamma distributions to explore their resemblance to observed distributions of certain quantity-goods in certain Social Aggregates and to generate ensuing distributions of justice evaluations.

evaluations—though they are different functions of the shape parameter c of the good's distribution and though they differ markedly in their slopes—are, nevertheless, monotonically related to each other. Thus, if we compare any two of the Exponentials that arise from Pareto-distributed goods, whichever one is the more desirable in terms of any characteristic will be the more desirable in terms of all the other characteristics. For example: the curve with the smaller Gini's mean difference will also have the smaller absolute magnitude on the lower extreme value, will also have the smaller absolute magnitude on the arithmetic mean, will also have the smaller percentage in the unjust underrewarded segment, and so on.

(2) Between families of curves, major parameters of the distribution of justice evaluations are not necessarily monotonically related to each other. Thus, if we compare any two curves, one need not be uniformly more desirable than the other in terms of all characteristics. For example, if we compare the Exponential curve that arises from a Pareto:$c = 2$ distribution with the Normal curve that arises from a Lognormal:$c = .6$ distribution (see Table 1), we find that the Normal's arithmetic mean (−.18) is of smaller absolute magnitude than the Exponential's arithmetic mean (−.1931), but that the Normal's Gini's mean difference (.6770) is greater than the Exponential's (.5).

Now, if we say that both the arithmetic mean and the Gini's mean difference of the distribution of justice evaluations are functions of the inequality in the good's distribution, then we quickly find ourselves in a logical contradiction, with opposing readings on which curve has the greater degree of inequality. One way out of this apparent contradiction is to substitute the term, "shape parameter c of the good's distribution," for the term, "inequality." For then we pay our respects, so to speak, not only to the wildly different shapes of different families of curves but also to the wildly different behaviors of their shape parameters.

But another, equally effective, way out of the apparent contradiction is to substitute the term, "several forms of inequality," for the term, "inequality." For the perspective embodied here suggests that there are many forms of inequality (not merely many measures of inequality) and that *each* form of inequality affects a different aspect of social life. That is to say, each form of inequality has for its special province some one social phenomenon. Thus, our conjecture is that social discontent depends on that form of inequality represented by the logarithm of the ratio of the geometric mean to the arithmetic mean of the good's distribution, that the propensity to violent revolutionary conflict depends on that form of inequality represented by the logarithm of the ratio of the lower extreme value to the arithmetic mean of the good's distribution, that political instability depends on that form of inequality represented by whatever distribution-dependent function of the shape parameter c of the good's distribution produces the Gini's mean difference of the distribution of justice evaluations, and so on. We know that these forms of inequality are indeed forms of inequality because their values would all be zero if the underlying distribution of the good were a Delta (or Equal) distribution.

Put differently, whatever parameter of the distribution of justice evaluations one is interested in minimizing (that is, whatever form of inequality one is interested in minimizing)—whether it be the magnitude of unjust underreward experienced by the "bottom" person (the Rawlsian criterion) or the mean experience of justice or injustice (the Benthamite criterion), or any other—if all the curves under review belong to the same distributional family, then there is but one uniform counsel: For distributions of justice evaluations that arise from Pareto-distributed goods, the curve with the higher value of Pareto's constant is the curve with the minimum values on all parameters of interest (that is, minimum values on all forms of inequality); for distributions of justice evaluations that arise from Lognormally distributed goods, the curve with the smaller value of the shape parameter c is the curve with the minimum values on all parameters of interest (that is, minimum values on all forms of inequality).

No easy solution, however, exists when

the curves under review belong to different distributional families. The curve with the best-off "bottom" person may have the largest percentage experiencing unjust underreward, as is the case with some pairwise comparisons from Table 1. In such cases, choice of a criterion parameter—that is, choice of the particular form of inequality to be minimized—becomes the paramount policy decision.[13]

◆

D. *A Note on Testing*

We now indicate the requirements for empirical testing of the specifications we have proposed.

1. Measurement and specification of the actual and Just terms.

The general theory asserts a measurement strategy and the Primitive model offers two probabilistic propositions. We now look at them.

(a) The measurement strategy

We suggested that individuals generally measure their Actual and Just terms as ranks if the good of value is a nonadditive, nontransferable quality-good and measure them in the good's own units if the good is an additive, transferable quantity-good. Thus, the testing task is to demonstrate that, when individuals evaluate the justice or injustice of their holdings of goods, the magnitude of their justice evaluation implies measurement of the terms in the way described here. Direct observation of individuals is required.

(b) The proposition on consensus about the good of value

The Primitive restriction that the members of a Social Aggregate value the same good(s) is a probabilistic proposition that states: Given a Social Aggregate, the majority of the members ($n > .5N$) value the same good or the same combination of goods. Direct observation of individuals is required.

(c) The proposition that justice is equality

The Primitive restriction that justice is equality is a probabilistic proposition that states: Given a Social Aggregate, given any good of distribution, the frequency distribution of Just terms held by the members has for both its arithmetic mean and its mode the arithmetic mean of the distribution of the good. Direct observation of individuals is required.

2. Specification of the justice evaluation function.

We have provisionally accepted the function we proposed earlier (Jasso; 1978). However, additional research in many different settings and about many different goods is needed. Testing of this function requires direct observation of individuals.

3. Specification of the behavioral consequences of the justice evaluation.

We suggested that social summary measures of individual-level phenomena as well as specifically social phenomena are functionally dependent on parameters of the distribution of justice evaluations. Tests of hypotheses, using the general theory, require observed frequency distributions of justice evaluations and, hence, data collected from individuals. Tests of hypotheses, using the Primitive version of the theory, require knowledge of the good or goods of value, their density functions, and their intercorrelations, and hence may be carried out *entirely* by means of documentary analysis and secondary analysis of existing data sets. Hypotheses should be tested both on cross-sectional data (i.e., on a sample of Social Aggregates observed at one point in time) and on time-series data (i.e., on observations within one Social Aggregate at different points in time). The central testing task is curve-fitting—that is, finding the equation for the best approximation to the relationship between a social phenomenon and a parameter of the distribution of justice evaluations—with this task repeated for as many specifications of as many dependent variables as one may like.

III. SUMMARY AND DISCUSSION

According to the theory of distributive justice here proposed, the natural and social goods have exogenously given distributions, and the individual makes exogenous selections of Goods to value, of Social Aggregates to form, and of the holding to consider Just for him/herself. The general theory makes few claims, but these claims are universal, applying uniformly to all humans: Briefly, the mathematical representation of self-appraisal about one's holdings of goods and of judgments about the just holdings of goods differs according to whether the good is a quality or a quantity, being ranks for the former and amounts for the latter; the experience of justice or injustice varies as the logarithm of the ratio of the actual holding to the just holding; this sense of justice is the primordial independent variable which determines variation in phenomena observable in individuals and in Social Aggregates.

---

[13] Choice of the form of inequality to minimize may indeed be the major question confronting many contemporary societies. Is it better to seek a high minimum in the distribution of wealth or of income, or to seek a smaller percentage below the arithmetic mean, or to seek a larger geometric mean? I am currently systematizing these alternatives and exploring the trade-offs in alternative redistribution strategies.

According to the theory, the social life may be regarded as basically a meeting of justice sentiments, and social variables may be explained and predicted by aspects of the distribution of justice evaluations. We offered several hypotheses—among them: that the Social Aggregate's propensity to violent revolutionary conflict varies with the absolute magnitude of the lower extreme value of the justice distribution; that the intensity of revolutionary violence varies with the higher of the two warring segments' arithmetic means; that the propensity to dissolution varies with the Gini's mean difference; and that social content/discontent varies with the overall arithmetic mean.

Variation in the social phenomena, both cross-sectionally and intertemporally, is attributable to differences in the distributions of justice evaluations. Due to the exogeneity of the actual distributions of goods and of the individuals' choices, one distribution of justice evaluations cannot be predicted from a prior one.

The sentiment of distributive justice bridges the gap between individualistic and collectivistic explanation; for it is experienced by the individual and measurable in the individual but, unlike hunger or thirst or fatigue, cannot even occur except by reference to the distribution of a good among a collection of humans. And though, according to the theory, we could predict all social phenomena of interest from an observed frequency distribution of justice evaluations, the explanatory terms used in the propositions would not be limited to simple aggregations of the individuals' scores (such as the arithmetic mean), but, rather, would also include other less simple attributes of the distribution, such as the Gini's mean difference. Conversely, prediction of the social phenomena is never possible solely from the actual distribution of goods, for the individuals' exogenous choices mediate the sense of justice; even in the Primitive version, the choice of goods must be ascertained before we can move from the good's distribution to the social variables. Thus, we cannot regard objective deprivation as synonymous with the experience of unjust underreward; the individual must make certain choices before he or she can experience unjust underreward.

The general theory is innocent of human choices and of the actual distributions of goods. And so it is possible for all members to feel justly treated or even for all to feel overrewarded. This is because they may value different goods or because they hold different notions of the just condition. An example of the former sort of Social Aggregate is found in Don Quijote's description of the eternal company of knights-errant (in the conversation which opens the first chapter of Part II); he names fourteen knights-errant, stating for each the attribute in whose distribution he ranks first; thus, the most courteous is Ruggiero, the most fearless is Rodamante, the boldest is Rinaldo, and so on. Examples of the second sort of Social Aggregate include medieval societies, the so-called "traditional" marriage, Augustine's ([413–426] 1952, *City of God,* Book 22, chap. 30) description of heaven, as well as Social Aggregates which follow the Marx-Blanc-Morelly (Marx [1875] 1959, *Critique of the Gotha Program*) or the koinonial (*The Holy Bible,* "The Acts" 2:44–5 and 4:34–5) prescriptions for the distribution of material goods.

But the Primitive version of the theory—by asserting consensus on the goods of value as well as the identity of equality and justice—extinguishes all possibilities, save one, for a Social Aggregate in which no one feels unjustly underrewarded. That remaining possibility is of an equal distribution of the good. Any departure from perfect equality produces a distribution of justice evaluations which includes some sentiment of underreward and some sentiment of overreward—and produces, as well, whatever empirical consequences follow from the parameters of the justice evaluation distribution.

In the Primitive model, the Social Aggregate is given and so all begins with the consensual choice of the good of value. If the good is a quality-good, then "everything" is determined "inside" the theory, and the principal independent variable is the size N of the SA; if the good is a quantity-good, then "everything" is determined "outside" the theory by the good's actual distribution, and the principal independent variable is the good's dispersion.

In the case of a quality-good, the good's density is fixed as Rectangular (or Discrete Uniform, for not-so-large Social Aggregates). For large N tending to infinity, the effects of N are obscured—most parameters, except the lower extreme value, quickly approaching the neighborhood of their limits. But for smaller sized Social Aggregates, the size N is a crucial determinant of the parameters of the distribution of justice evaluations. As N increases, the absolute value of the overall arithmetic mean increases as does the value of the Gini's mean difference—and with them, we hypothesize, the magnitudes of social discontent and of the propensity to dissolution. In the determination of the proportion underrewarded and of the mean of the underrewarded segment, we find a special attentiveness to whether N is odd or even—the proportion underrewarded being a nondecreasing function of N, and the mean of the underrewarded segment varying as two distinct decreasing sequences, one on the set of even integers, the other on the set of odd integers (both converging to a limit of $\ln 1/e$ or -1), so that given any two adjacent integers, the odd-sized Social Aggregate has the larger absolute mean of the underrewarded segment.

In the case of a quantity-good, the crucial determinant of social variables is the inequality in the good's distribution (quantified in the Pareto and Lognormal families as the shape parameter c). General inequality is not comparable across distributional family, though particular manifestations of inequality are. Thus, we show that, within distributional family, all social variables vary with the shape parameter c; while across distributional family, one particular distribution may have a greater magnitude of, say, the Gini's mean difference (and, we hypothesize, of political instability) than a second; but the second may have a larger absolute magnitude of, say, the lower extreme value (and, we hypothesize, of the propensity to revolution) than the first.

Put differently, in the Primitive world, selection of a quality-good is the scope condition for the operation and activity of the size N of the Social Aggregate, and selection of a quantity-good is the scope condition for the operation and activity of the quantity-good's actual distribution. In both cases, the "true" explanatory variables are parameters of the justice distribution. However, in the quality-good case, the size N can be used as proxy independent variable, and in the quantity-good case, a measure of inequality can be so used, provided that all cases in the analysis belong to the same distributional family. Ignoring these conditions produces specification error and obscures the underlying relations. Of course, such specification error can be averted by using the appropriate terms from the justice distribution, rather than N or c.

One major task in developing this theory is precisely to expand the matrix depicted in Table 1 by evaluating the parameters of interest in many more distributional families. We are currently adding rows to the matrix—for example, one set for the Asymmetrical Laplace family of curves that results from consensual valuation of one quality-good and one Pareto-distributed quantity-good and another set for the negatively skewed Gamma family of curves that results from consensual valuation of two or more quality-goods. And we are adding columns to the matrix—for example, one for the mean of the special function defined as the arc secant of the justice evaluation, for justice evaluations less than or equal to −1, or greater than or equal to +1, and zero elsewhere.

The Primitive model may be viewed as a quantitative representation of some of Hobbes's [1651] 1952 *Leviathan*, chaps. 13–5,17) brilliant insights—for example: that "equal distribution is the law of nature"; that "when all is reckoned together the difference between man and man is not so considerable as that one man can thereupon claim to himself any benefit to which another may not pretend as well as he"; that "if any two men desire the same thing, which nevertheless they cannot both enjoy, they become enemies"; and that "men are continually in competition for honour and dignity . . .; and consequently amongst men there ariseth on that ground, envy, and hatred, and finally war."

In terms of the Primitive model, if the distribution of the good of value is unequal, consensus breeds scarcity. It is precisely this consensus on the goods of value that engenders the competition about which Hobbes writes.

Although Hobbes depicted powerfully the state of human society when the good of value is a quality-good, and anticipated, as well, some features of human society when the good of value is a quantity-good, it was Marx who brilliantly explored the personal and social consequences of alternative distributions of material resources (e.g., Marx [1859] 1913, *A Contribution to the Critique of Political Economy*). It was Marx whose writings compelled us to think about human sentiments and social relations when "everything" depends on the actual distribution of a quantity-good. Thus—and simplifying greatly—we may regard Hobbes as the prophet of life in a quality-good regime and Marx as the prophet of life in a quantity-good regime.

Perhaps the most striking result of this theory concerns the cross-distributional consequences of economic inequality. Across families of probability distributions, the distribution with the smaller value on one manifestation of inequality may have the larger value on another manifestation of inequality. Thus, actions to decrease one form of inequality may serve to increase another. And, since each form of inequality is viewed as exercising hegemony over a special area of social life, mitigating one consequence of inequality may serve to exacerbate another. Thus, the paramount policy decisions center on the choice of the form of inequality to minimize.

But now we must turn from the task of formulating the theory to the task of testing it. Now we must look at the many conjectures we have described and ask how faithful a likeness they are to the social reality we wish to approximate.

SEXUAL EMBOURGEOISMENT? SOCIAL CLASS AND SEXUAL ACTIVITY: 1938–1970*

MARTIN S. WEINBERG

American Sociological Review 1980, Vol. 45 (February):33–48

Using the idea of "embourgeoisment," as it appears in stratification literature, that working-class people are increasingly adopting middle-class values and behaviors, this paper examines changes in the relationship between social class and sexual behavior over the last thirty years. Comparing data collected in 1938–63 with data collected in 1969–70, we find the following: For males, there are now similarities between the working and middle classes with regard to the incidence of various sexual activities, but differences exist for age at first experience, number of opposite sex partners, and the incidences and frequencies of adolescent sexual activities. For females, there were similarities between classes in the past, but now we find differences between the two classes regarding age at first experience, reactions to first experiences, and the incidences and frequencies of adolescent sexual activities. We have concluded that these findings offer little support for the idea that the sexual patterns of the classes have become indistinct. Social class is still seen as an important determinant of sexual behavior.

There can be no doubt that our society has experienced substantial change in its macrostructure. Over the last two generations the United States has undergone momentous events such as the social dislocation produced by a world war, as well as less explosive but no less important trends such as increasing affluence, urbanization, and so on. Sociologists have long been interested in such changes—at the societal level and in their effect on individual lives. Often there is disagreement, however, on the extent and character of the presumed consequences. This is also true in the area of sexual attitudes and behavior. Thus, for example, we find Reiss (1974:311) commenting on recent social change:

> When most people have no real problem in obtaining food, clothing and shelter, and even many of the luxuries, then the stage is set for them to devote their energies to issues concerning the quality of life. . . . Our sexual customs are changing in accord with the emphasis . . . on the quality of human relationships. . . .

In contrast, Gagnon and Simon (1970:110–3) state:

> The litany of technological, scientific, economic and social changes in (our) society is nearly endless. . . . Part of all this change has been events that everyone thought must surely lead to vast changes in sexual behavior. . . . (But) the reason why there was *not* any (such) change was that many of the things that were thought to have something to do with sex didn't have anything to do with it.

Unfortunately, such issues are difficult to resolve because data are not available. Not only do we lack data that would adequately describe earlier sexual patterns, but sex research has not progressed to the extent that we have adequate data for the contemporary situation. Moreover, where such a conjunction of past and present data exists, we find that the data are not directly comparable. Nonetheless, it is often possible to chart, in a general way, the effects of major social changes. Indeed, our choice is between making use of imperfect data and hoping for additional research or providing even more speculative descriptions of the shape of social change.

This paper examines changes in the relationship between social class and sexual behavior in an attempt to elucidate the

effects of our changing class structure on sexual life over the last thirty years. Specifically, we shall be examining the "embourgeoisment" thesis with regard to sex. In its general form this states that, as a result of a rising standard of living since World War II, "the traditional dividing line between manual workers and white collar employees no longer holds because large segments of the working class now share a 'white collar' style of life and many also accept middle class values and beliefs" (Mayer, 1963:467).[1] If this is true, one might expect a convergence between middle-class and working-class patterns of sexual behavior. This is directly stated by Delora and Warren (1977:542–3):

> . . . the culture of the lower classes and of ethnic minorities is undoubtedly influenced somewhat by the mass media and by contact with middle class society through education and other social institutions. To the extent that lower class sexual behavior and attitudes differ from those of the upper classes . . ., we can expect lower class sexual interaction to continue to become increasingly like the white middle class standard.

Such a position is also taken by Rainwater and Handel (1963) who argue that the traditional working-class family has radically changed and become more like the middle-class family in the face of increasing affluence. This change, they maintain, has taken the form of the nuclear family becoming more important than the extended family with the result that the modern working-class family is characterized less and less by marital role segregation. Consequently, this greater cooperation and solidarity among spouses, as in the middle class, allegedly increases their level of intimacy and hence their sexual satisfaction. Again, then, we confront the assertion that the working class is adopting middle-class patterns of sexual interaction.[2]

Finally, the work of Schmidt (1977) divides the working class into stable and unstable levels (defined mainly on grounds of economic insecurity), and notes that there is a basic similarity between the sexual patterns of adolescents from the stable working class and the middle class.[3]

Thus, many authors suggest that not only has there been an embourgeoisment of large sections of the working class that has influenced many social attitudes and values, but that this process has also intruded into the most intimate aspects of personal life, in this case, sexual behavior. Furthermore, embourgeoisment, they assume, will proceed unabated if present trends continue so that contemporary societies will eventually develop a common sexual ethic with little or no variation in sexual patterns by social class. Wilensky (1964:180) has summarized the overall outcome succinctly:

> Thus, we may assume that the influence of mass education, the media, and the centralized state will in the long run overcome the influence of variations in work, religion, age, and locality as sources of cultural values and leisure styles and we can expect mass culture in both Europe and America to penetrate structures now more or less insulated from it.

This paper will present data on the relationship between social class and sexual patterns during two time periods in an attempt to examine to what extent embourgeoisment has taken place, and, thus, in this realm, how social classes have or have not insulated their members from intrusive social forces. That is, to what extent will our data delineate two distinct, as opposed to two similar, sexual life styles between the working and middle class?

DATA AND METHODS

For the earlier time period, we use data collected by Alfred Kinsey and his associates. The data collection began in 1938 and continued through 1963. (Approximately one-fifth of the 5,460 white male interviews were carried out after publication of the male volume in 1948 and 2% of the 5,386 white female interviews after publication of the female volume in 1953.)[4] The bulk of the data, however, is from the 1940s (94% of the male interviews and 98% of the female interviews).[5]

---

[1] Other sociologists whose names have been associated with the "embourgeoisment" thesis are Dahrendorf (1964), Mills (1959), Lenski (1963), Ginsberg and Berman (1963), Zweig (1961), and Wilensky (1964).

[2] To quote Rainwater and Handel (1963:73), " . . . the working class couples in our family planning study with less segregated conjugal-role relationships are indistinguished from the middle class couples in their patterns of sexual relations, but are quite different from working class couples who have highly segregated role relationships."

[3] However, his data do show important differences between these groups (Schmidt, 1977). Note, too, that other writers strongly assert the existence of a differentiated working class (cf., Miller, 1964; Hamilton, 1963; MacKenzie, 1973).

Although these data have been criticized for their unrepresentativeness, they do constitute the most comprehensive set of data on sexual behavior for that period.[6] Moreover, we present data from what is referred to as the Kinsey Basic Sample (Gebhard and Johnson, 1979), a sample "cleaned" of persons derived from sources with a known sexual bias, for example, prostitutes. Also absent from this sample are prisoners who, it has been criticized, bias the working-class respondents (Sagarin, 1973). We present for the first time, therefore, analysis of the Kinsey et al. data from a sample that has been greatly improved.

For the more recent time period, we rely on data collected in 1969–70 by the Institute for Sex Research in connection with a large scale study of homosexuals from the San Francisco area (Bell and Weinberg, 1978). In an effort to provide a control group for comparison with the homosexuals, a sample of 284 white males and 101 white females from San Francisco's general population was obtained through the use of probability sampling with quotas. Random probability sampling was used to select census tracts and city blocks within the chosen tracts. Quota sampling was then used within each block to provide representation for various race, age, sex, and education categories.[7]

We are, however, unable to determine the representativeness and comparability of the San Francisco and Kinsey Basic Samples. For example, we do not know how the respondents in San Francisco may differ from respondents in other locales. Confirmations of prior research, however, with regard to a variety of locales (e.g., Weinberg and Williams, 1975, which includes San Francisco and other locales in three Western countries), have made us optimistic with regard to the generalizability of sexual patterns. For example, in the above study, not only did we find the same distribution of different degrees of homosexuality, but also we found that data on sexual practices and sexual frequencies showed no appreciable fluctuations among any of the European and American locales. Similarly, sociological relationships were replicated over locales. In the case of heterosexuality, we see no prima facie reason why replications regarding relationships would also not appear. This should especially be so since our independent variable, social class, is a major influence on social behavior. Such replication is even more likely when such locales are situated in the same society and share common economic and educational institutions. As with most research, however, we look forward to replications with other samples.

The form of our analysis is as follows. First, we computed zero-order Pearsonian correlation coefficients between social class and sexual behavior separately for males and females from the Kinsey Basic Sample. An F probability of .05 was the criterion for statistical significance and an r greater than .10 was the criterion for substantive significance.

Next, we did the same thing for the San Francisco Sample. Then, we compared the correlations between the two different time periods to see which, if any, changes emerged. The z_r transformation for r was used to test for the statistical significance of the difference between the two values of r (Edwards, 1976:89–90). (We have not been able in every case to make comparisons between the two studies; for example, there sometimes are data provided by one study that were not collected in the other. These additional data, however, are often used because they are relevant to our research question and valuable in illustrating global points in our argument.) All these procedures involved whites only. To check for spurious relationships, partial correlation coefficients were run controlling for age, marital status, age at first marriage, and religiosity. Tables of means and percentages are also provided for the reader to compare more closely the nature of the relationships represented by the correlations.

---

[4] One hundred and eighty-five of the male interviews and 58 of the female interviews were carried out by Kinsey's associates after his death in 1956.

[5] In the Kinsey Basic Sample the number of white males interviewed each year from 1938–63 is as follows: 1938, 30; 1939, 429; 1940, 516; 1941, 217; 1942, 220; 1943, 132; 1944, 727; 1945, 721; 1946, 413; 1947, 471; 1948, 855; 1949, 391; 1950, 25; 1951, 23; 1952, 20; 1953, 32; 1954, 31; 1955, 16; 1956, 6; 1957, 4; 1958, 31; 1959, 18; 1960, 121; 1961, 7; 1962, 3; 1963, 1. For females the corresponding numbers are: 1938, 1; 1939, 93; 1940, 149; 1941, 82; 1942, 83; 1943, 380; 1944, 747; 1945, 1,017; 1946, 462; 1947, 336; 1948, 999; 1949, 914; 1950, 15; 1951, 11; 1952, 3; 1953, 9; 1954, 16; 1955, 8; 1956, 3; 1957, 6; 1958, 3; 1959, 7; 1960, 35; 1961, 4; 1962, 2; 1963, 1.

[6] For critiques of Kinsey et al.'s methodology, especially the sample, see Wallin (1949); Hobbs and Lambert (1948); Cochran, Mosteller and Tukey (1953).

[7] For additional details about the sample and sampling procedure, see Bell and Weinberg, 1978:37–9.

Kinsey et al. (1948) used two measures of social class in their work: occupational level and educational achievement. They found that, where both were used systematically, there was little difference in the results produced. At the same time, Kinsey et al. (1948:330–1) noted that "educational level . . . [is] the simplest and best-defined means for recognizing social levels. . . . Occupational classes are more poorly defined than educational-levels." The San Francisco study also has both measures, and we, as well, chose to make our comparisons using educational attainment as the measure of social class, principally because it produced (as for Kinsey et al.) the least ambiguous results.[8] (One source of ambiguity remains, however—the lack of a clear dividing line between the social classes. This problem exists, though, with most indicators of social class and for lay people as well as for social scientists; cf., Kinsey et al., 1948:332.) Finally, we believe, as both Delora and Warren and Wilensky have suggested, that education is a key variable through which the culture of the working class has been modified. While Kinsey et al. (1948) split their educational groups into 0–8 years, 9–12 years, and 13+ years, we divided both their and our sample into high school or less, some college, and four or more years of college. This modification was made because of changes in levels of educational attainment which produced the small N for the 0–8 group in the San Francisco Sample.

RESULTS

Males

The Kinsey Basic Sample. A generation ago, Kinsey et al. (1948) found a relationship between social level and the sexual patterns of males. One finding was that lower level males were more restricted in their sexual practices. According to Kinsey et al. (1948:369):

> The record is . . . one of more extended pre-coital play at the upper levels, and of a minimum of play at the lower levels. Many persons at the lower level consider that intromission is the essential activity and the only justifiable activity in a "normal" sexual relation.

Thus, in terms of petting behaviors (for example, manual stimulation and oral-genital contact) there was a higher incidence of these behaviors among the more educated males (Table 1A). For instance, 61% of the high school group and 69% of the some college group, but 87% of the college group had masturbated a female (r = .24***), with 56%, 59%, and 80% of these respective groups having been masturbated by a female (r = .23***); approximately a seventh of the high school group and some college group, as compared with a third of the college group had performed oral-genital contact (r = .20***); and approximately a fifth of the high school group and some college group, as compared with 37% of the college group, had received oral-genital contact (r = .18**) (Table 1B). (Unfortunately, Kinsey et al. did not systematically obtain *frequency* data for these various behaviors.) Finally, Table 1A shows that in the Kinsey et al. data social class was a marked determinant of male sexual experience but not of female.

---

[8] Both samples are biased in the direction of higher class respondents. For example, for both males and females, among the San Francisco respondents, 25% had had high school or less, 33% some college and 42% a college degree or more.

† Dash will indicate no such data from Kinsey et al.

A second finding was that less educated males had experienced sexual intercourse at an earlier age (Table 2A). As Kinsey et al. (1948:349) note:

> College males are very slow in arriving at their first pre-marital intercourse, and a comparison . . . indicates that, on an average, they do not have their first experience until . . . [several] years after the lower level males start.

The average age at first coitus was 17.3 for the high school group, 17.8 for the some college group and 20.5 for the college group (r = .32***) (Table 2B).[9] Table 2A also shows that in the Kinsey et al. data, for males, social class is a stronger correlate of the age of first coitus and first orgasm in sleep than it is for females.

A third finding was that among those males who had premarital intercourse the less educated had more premarital coital partners than did the better educated (Table 3A). Kinsey et al. (1948:349, 383) say:

> A good many college males never have pre-marital intercourse with more than the one girl whom they subsequently marry. . . . Lower level males [on the other hand] . . . are often highly promiscuous in their choice of pre-marital partners, and there are many who have no interest in having intercourse with the same girl more than once.

Table 3B shows that the average number of premarital sexual partners was 18.9 for the high school group, 10.5 for the some college group and 9.6 for the college group (r = −.11***).

With regard to all the above results, Kinsey et al.'s (1948) explanation was that working-class males were more likely to see coitus as natural, whereas other sexual techniques were more likely to be seen as a perversion. Thus, their earlier age at first coitus, greater number of partners,

---

[9] In addition, in all classes, sexual behaviors are begun at an earlier age now than in the past. Also, the San Francisco sample shows that at all social levels, oral-genital relations are experienced initially at a later age than is coitus. (No similar data are available for Kinsey et al.)

and more restricted sexual practices were characteristic of the working-class males.

The San Francisco Sample. The San Francisco results for 1969–70 clearly differ from the Kinsey et al. findings for the 1940s in that, for males, social level is no longer significantly correlated with having ever experienced particular sexual acts (Tables 1A and 1B). (One exception is nocturnal emissions, r = .15**.) Furthermore, they differ from the Kinsey et al. data in showing that social class now no longer has a differential effect on the sexual incidences of males vs. females (Table 1A).

In general, such class convergence among males, however, appears to be limited to incidence. Social level is still related to other dimensions of sexual experience. Our current data, for example,

Table 3A. Zero-Order Correlations between Social Level and Number of Opposite Sex Partners†

	Males		
Sexual Activity	Kinsey et al. Sample	San Francisco Sample	Z Level
Number of Opposite Sex Partners	−.11*** (3297)	−.19*** (284)	n.s.

	Females				
Sexual Activity	Kinsey et al. Sample	San Francisco Sample	Z Level	Kinsey et al. Male-Female Z Level	San Francisco Male-Female Level
Number of Opposite Sex Partners	.02 (1876)	.04 (101)	n.s.	***	*

† Kinsey et al. dependent variable is number of premarital coital partners. San Francisco dependent variable includes marital, extramarital, and premarital partners with regard to oral-genital activity, coitus, and masturbation.

Table 3B. Social Level and Mean Number of Opposite Sex Partners[†]

	Males					
	Kinsey et al. Sample			San Francisco Sample		
	Educational Level					
Sexual Activity	HS	SC	C	HS	SC	C
Number of Opposite Sex Partners	18.9 (389)	10.5 (830)	9.6 (1895)	12.8 (71)	13.6 (95)	7.7 (118)

[†] Kinsey et al. dependent variable is number of premarital coital partners. San Francisco dependent variable includes marital, extramarital, and premarital partners with regard to oral-genital activity, coitus, and masturbation.

show that the less educated males (viz., those who were not college graduates) are more likely to have initially experienced *all* the studied sexual behaviors (except nocturnal emissions) earlier than did better educated males (Tables 2A and 2B; comparable data are not available from Kinsey et al. for petting and oral-genital activities). Kinsey et al. (1948:349, 551) found this to be the case only for coitus (our criteria for substantive significance exclude the masturbation and nocturnal emissions' relationships—r = .06*** and −.09***, respectively). Lower level males, therefore, no longer seem to have an aversion to petting techniques and are engaging in them, as they do coitus, at a relatively early age. (Age at first marriage does not explain these findings.) Thus, in the San Francisco Sample, the average age at first coitus is 16.7 for the high school group, 17.3 for the some college group, and 18.9 for the college group (r = .27***); for the first experience of masturbating a female or being masturbated by a female, the mean ages are 17.4 and 17.3 for the high school group, 17.0 and 17.9 for the some college group, and 19.1 and 19.5 for the college group (r = .17**, r = .22**); for cunnilingus, 20.4 and 20.1 years of age for the high school group and some college group and 22.1 years of age for the college group (r = .14*); for being fellated, 18.9 for the high school group and some college group and 21.1 for the college group (r = .21***).

In addition, the San Francisco data show that less educated males still have more sexual partners—12.8 for the high school group, 13.6 for the some college group, and 7.7 for the college group (r = −.19***) (Tables 3A and 3B). (It should be noted here that compared with the Kinsey et al. data this is only an indirect comparison. Their "number of sexual partners" refers only to premarital coital partners whereas the San Francisco variable includes marital and extramarital partners in addition to premarital partners, and masturbation and oral-genital activity in addition to coitus. It is interesting, however, that even with a broader definition of "partners" and sexual behaviors a similar relationship is found.)

Finally, our current data on the incidence and frequency of male sexual activities between the ages of 14 and 17 (comparable data are not available from Kinsey et al.) show that during these years less educated males had a higher incidence and frequency of both petting and sexual intercourse than did better educated males (Tables 4A-4D).[10] For example, the high school group and some college group had four times the frequency of the college group in coital activities during these years (r = −.23***) (Table 4D). Tables 4A and 4C also show that social class had no differential effect on adolescent sexual patterns (incidence and frequency) of males vs. females.

In sum, with regard to social level, male sexual patterns show two types of convergence over the last generation or so. On the one hand, there is a *between-class convergence;* namely, working-class males are more like middle-class males in *incidence* of various sexual experiences. On the other hand, there is a *within-class*

---

[10] We did not arbitrarily choose the age range 14–17. This was part of the wording of the questions asked in the San Francisco study.

Table 4A. Zero-Order Correlations between Social Level and Incidences of Sexual Activities between the Ages of 14 and 17 (San Francisco)†

	San Francisco Sample		
Sexual Activity	Males	Females	Z Level

Sexual Intercourse	−.23*** (284)	−.39*** (100)	n.s.

† No such data from Kinsey et al.

convergence; namely, the effects of social level assert themselves to make *age at first sexual experiences and incidence and frequency of adolescent petting behaviors* consistent with the earlier Kinsey et al. findings for coitus. In addition, we still find, as did Kinsey et al., an inverse relationship between social class and number of sexual partners.

In general, other data from San Francisco show no differences between males from different social levels in adult frequencies for specific sexual activities; in positive or negative reactions to the first or last time the respondents had various sexual experiences, or in the last age at which they engaged in the particular sexual activity.

Females

The Kinsey Basic Sample. The findings of Kinsey et al. (1953) on the incidence of various sexual behaviors of women from different social levels stand in strong contrast to what was found for men. Given our criterion for substantive significance (r > .10), there was only one significant difference—higher level females were somewhat more likely to have ever masturbated (Tables 1A and 1B).[11] However, as expressed in correlational terms, this is far from a strong relationship and not much stronger than those found for other sexual outlets. In essence, then, in the 1940s, social level did not distinguish the incidence of various sexual experiences of women. Moreover, according to Kinsey et

---

[11] The strongest relationship they found between social class and sexual activity for females was in the case of homosexuality (Kinsey et al., 1953:459)—viz., a greater incidence of homosexuality was found among the highest educational groups.

al. (1953), not only is there no relationship found between social level and sexual incidence for women, but also there is none for other dimensions of sexual experience as well. (One exception which Kinsey et al. did not discuss was the earlier age for first coitus among lower level females; $r =$ .18***)[12] (Tables 2A and 2B; 3A and 3B). Kinsey et al. (1953) attributed this lack of relationship to female sexuality being less conditionable than male sexuality (cf., Robinson, 1976:102, 110) in that not only social class, but also most of the other social factors affecting male sexuality were inoperative in the case of women.[13] As Kinsey et al. (1953:649–50) say:

> In general, males are more often conditioned . . . by a greater variety of associated factors than females. . . . It is highly significant to find that there are evidences of such differences between the females and males of infra-human mammalian species, as well as between human females and males.

The San Francisco Sample. Our first set of findings for San Francisco women are similar to what Kinsey et al. (1953) found in the 1940s: viz., no significant relationship between social level and the incidence of various sexual behaviors (Table 1A). (Masturbation does, however, relate

---

[12] Reiss (1965) has also pointed this out. An additional difference that Kinsey et al. (1953:378–9) did point out, but which did not affect their conclusions, was the small positive relationship between educational level and rate of marital orgasm ($r =$ .04*).

[13] This was not quite the case, however, as religiosity and generation showed marked effects on female sexuality (cf., Robinson, 1976:102).

to social level as in the Kinsey et al. data.)[14]

Unlike Kinsey et al. (1953), though, our data show that social class differences in female sexuality do exist with regard to other dimensions. For example, we now find that lower level females experience oral-genital sex (fellatio, r = .19*; cunnilingus, r = .24*) and coitus (r = .38***) at an earlier age than do higher level females (Tables 2A and 2B). Kinsey et al. (1953) found this only for coitus which, as previously mentioned, they failed to discuss. We also find that there is an inverse relationship between social level and sexual incidences and frequencies between the ages of 14 and 17 (Tables 4A–4D). That is, during these teenage years, less educated females were more likely to experience petting and expecially coitus (r = −.39***), and to experience them more frequently, than did better educated females. We propose that these findings signify a broadening within-class convergence: namely, lower level females are "catching up" to lower level males—diverging from higher level females—in terms of age at first experiences and incidences and frequencies of early sexual activity.

Another finding from our current data concerns the way females reacted to their first sexual experiences. As shown in Tables 5A and 5B, where such differences are found, it is upper level women who are more likely to report positive feelings toward a variety of initial sexual experiences. Thus, for example, the strongest differences show 40% of the high school

‡ Only significant relationships (cf. Table 5A).

---

[14] As an aside, there is an overall increase in oral-genital activity for both men and women: for Kinsey et al. 19% (HS), 19% (SC), and 37% (C) of the males had been fellated at least once, while in the San Francisco Sample the respective percentages are 80, 83, and 83; for females the respective percentages of those who had ever performed fellatio were 31, 16, 34, in the Kinsey et al. data and in the San Francisco Sample 64, 74, 74.

group and 44% of the some college group as compared with 73% of the college group reacting positively to their first masturbation experience (r = .24*) and 19% of the high school group as compared with 46% of the some college group and 51% of the college group reacting positively to the first experience of masturbating a male (r = .32***). Again this might be interpreted as a broadening within-class convergence. In the Kinsey et al. (1948:367–74) sample, middle-class males, for example, responded more favorably to masturbation, petting techniques, a variety of coital positions, etc., than did working-class males. Thus, our contemporary middle-class women show similarities to the middle-class men in the 1940s in their acceptance of a larger range of sexual experiences.[15] Rainwater and Handel's (1963) hypothesis would suggest that more positive responses among middle-class females might be a result of greater role integration among men and women, married or unmarried. We should also note LeMasters's (1975) vivid evidence that working-class males prefer to be segregated from females.

In general, no differences were found among the San Francisco women from different social levels in age at last experience of various sexual activities, adult frequencies for specific sexual activities, number of sexual partners, or positive or negative reactions to their most recent sexual practices. Finally, we should note that despite some large differences between the correlations for San Francisco males and females, few are statistically significant.

Male and Female Differences over Time

Kinsey et al. (1953) made much of the fact that social level distinguished the sexual patterns of males but not females. Thus, for the Kinsey et al. data, there are significant differences between the social class relationships for men vs. women with respect to various dimensions of sexual experience. In contrast, our more current data show that social level affects the sexual patterns of both males and females and in similar ways. Thus, in the San Francisco Sample there are no significant differences between the social class relationships for men vs. women with respect to incidence, age at initial sexual experiences, incidence and frequencies of adolescent sexual activities, and positive reactions to initial sexual experiences. Since in all cases Kinsey et al. (1953) did not obtain comparable data, we do not know if some of the same patterns we found were also characteristic of the 1940s. If, as they suggest, these patterns were not evident then, our findings represent a true change. Contrary to Kinsey et al. (1953), though, we believe that any lack of social class effects with regard to these variables would have resulted from the common socialization experiences of females, not, as they maintained, because women are less sexually conditionable. Regardless of their social level, this socialization discouraged women's sexual expression even more in Kinsey's era than in the late sixties (cf., Klassen et al., forthcoming). Thus, it is our belief that in the 1940s *gender* outweighed *social level* in the determination of female sexual patterns.

Today, female sexual expression is more accepted. As our results indicate, the role of gender seems to have been attenuated somewhat and other factors allowed to come into play that have effects on sexual patterns. With these changes, the sexuality of females has taken on some of the features that characterize males of the same social class. Thus, social class now competes with gender in the determination of female sexual patterns.

CONCLUSIONS

The preponderance of evidence we have been able to assemble leads us to conclude that there has been no strong embourgeoisment of sexual patterns since the 1940s. The limited embourgeoisment we found has been among males for whom social class no longer distinguishes what type of sexual behaviors they will experience. Aside from this, social class is important among males with regard to the age at onset of various sexual behaviors as well as incidences and frequencies of these acts during adolescence. For females, social class is related to early sexual activity and to positive feelings toward various first sexual experiences.

---

[15] We thought that this might be related to the later age at which they begin their sexual activity. Controlling for initial age, however, did not affect the relationship.

The class differences we find seem to have a consistent logic: a movement we have described as within-class convergence. The uniqueness of class-related styles of sexuality, discovered by Kinsey et al. (1948; 1953), appears to have widened and become more consistent rather than disappearing into some general sexual pattern shared by most Americans.

These findings are in line with other empirical studies of embourgeoisment, most of which show that strong class differences still remain in modern affluent societies (cf., Goldthorpe et al., 1968a; 1968b; 1969; Glenn and Alston, 1968; MacKenzie, 1973). Some of the reasons that have been suggested for the continuing influence of social class can be applied to our findings.

One, favored more by left-wing European sociologists, is that structural differences still exist in the larger society that make the economic situation of the classes different. Thus, for example, despite increases in the standard of living, the working class still lags behind in earnings, job security, occupational mobility, fringe benefits and hours worked (Rinehart, 1971). This is especially the case for those at the bottom of the working class. Schmidt (1977:289) has written that a " . . . certain socio-economic level is a prerequisite for emotionally satisfying and mutual sexual relations enjoyable for both partners" so that the effects of insecurity, poverty and joblessness ruin sexuality.[16] This is no doubt true for that section of the working class he refers to as the "unstable" working class. It is unlikely, however, that he is referring to the level of working-class people in our current sample.

Furthermore, one need not take a deprivation approach with respect to structural factors, especially when dealing with the upper levels of the working class.[17] MacKenzie (1973) suggests that we must stress not income but a person's position in the division of labor. His study of affluent construction workers shows them to be far from economically deprived yet to reflect distinct working-class traits because of their location in the division of labor. This is seen to have important consequences in how they socialize their children. In line with Kohn (1969), he sees working-class parents as emphasizing conformity, respect for others, and good behavior consistent with jobs that require few decisions. This is in contrast to middle-class socialization, which inculates values of self-confidence, innovation, and perseverance, all of which are important to middle-class occupations. One would imagine that such varying values could also affect sexual patterns. Deferred gratification, for example, has been frequently cited for its role in delaying middle-class sexual activities (cf., Kinsey et al., 1953; Linderfeld, 1960).

At the same time, it is difficult to see how structural factors per se can account for our findings. (For example, they seem at odds with the lower class deprivation hypothesis unless one were to explain the precociousness of working-class adolescent sexual behavior in terms of ineffectual homes caused by economic pressures on the parents. In addition, controlling for age at marriage, a class-linked structural characteristic, does not change our findings.) Structural factors do, however, seem important in isolating or insulating the working class from a variety of influences.

---

[16] He also writes (Schmidt, 1977:289) that " . . . the socioeconomic situation of an individual is one of the most powerful and basic variables correlating with the sexuality of an individual, though the exact relationship of cause and effect is unknown."

[17] Schmidt (1977:293) does, however. He writes that the working conditions of the stable working class " . . . are manual, often physically exhausting activities that must be performed to earn a living and which do not provide much satisfaction or self actualization, and no station or prestige. These conditions make it very difficult for people to approach and conceive of sexuality as something playful that can be enhanced with fantasy. For them sex, much the same as eating, is a serious and direct fulfillment of a physical need. . . . Within the middle class, on the contrary, the process of fulfillment is artfully delayed, refined beyond the physical body-to-body aspect and maximized." (This contrasts with the basic similarities he claims exist between adolescents from the stable working class and middle class.)

This relates to a second major reason given for the persistence of class differences and an answer favored more by American sociologists. This position sees classes as cultural groups, more or less separate from each other, each enjoying a distinct style of life.[18] What these studies of social class strikingly demonstrate is the persistence of social attitudes and values over time (Shostak, 1969; Miller and Riessman, 1961; LeMasters, 1975; Miller and Simon, 1974). There certainly is a structural base to these class cultures (as, for example, MacKenzie [1973] and Rainwater and Handel [1963] have demonstrated), but investigators are more likely to emphasize cultural determinism in their explanations. We would argue that the class differences found in our study are best explained in this way, although the structural basis of these class cultures should not be ignored (for example, when young adults find themselves in college rather than in the labor force). Moreover, such structural factors operate to segregate the classes from each other and allow them to retain their unique cultural character. (At the same time, however, most of this segregation is probably self-imposed; the classes simply do not want to mix or adopt the life styles of one another.) Thus old meanings persist. For the working class, sex is still seen as something natural, to be engaged in as early as possible. What social change has occurred suggests that working-class females are now coming to share some of the working-class males' sexual patterns.[19] In addition, the working-class male has extended his sexual repertoire since Kinsey et al.'s time, but in the same class-prescribed manner in which he previously pursued coitus. For the middle class, sex is still deferred more. Middle-class men and women both start sexual activities at a later age and have less sex during adolescence than do working-class men and women. In addition, more middle-class than working-class women enjoy their first sexual experiences.

The link between class and sexual patterns still remains, we believe, because social classes as cultural groups have not really changed. We propose that the following has occurred:

1. Greater affluence (e.g., more TVs, cars, suburban houses, etc.) produces only surface changes among the working class. It creates a working class with all the accoutrements of an improved standard of living, but it does not produce a working class that has changed its values simply because it has become less distinguishable from the middle class in terms of its consumption patterns. Old values still remain and are used to interpret those surface changes so that the new is absorbed into the old.

2. A similar process probably occurs also in the case of the mass media and its supposed influence. The two-step flow of communication still operates so that middle-class messages are filtered through other working-class people and not transmitted directly to atomistic individuals (cf., LeMasters, 1975:142–3).

3. So-called embourgeoisment influences do not seem to have affected working-class behavior in other areas (e.g., political behaviors, cf., Goldthorpe et al., 1968b), so why should we expect them to affect sexuality? Social classes still remain segregated from one another, which limits middle-class influences. Moreover, if knowledge of others' sexual patterns is characterized by "pluralistic ignorance" (Gagnon, 1965), there is little that has altered this. That the sexual content of the media has increased does not necessarily change things. In addition to

---

[18] Reiss (1965:756), for example, states, "My interpretation of the relation between social class and permissiveness suggests that in studies of this sort social class data should be refined to produce groups that actually share a common style of life. People who share a generally liberal or conservative attitude are more likely to have similar attitudes toward sex than are people who merely earn the same salary or have gone to school the same number of years, though of course style of life is in part a consequence of income and education."

[19] Whether the change in working-class women's sexual patterns means they enjoy sex more or are coerced into it more by males, we do not know. Other studies suggest the latter interpretation (Rubin, 1977).

the filtering effect of the two-step flow of communication, class and gender socialization are far more powerful than the influence of the media (Rubin, 1977).

4. Most of the emphasis in studies of embourgeoisment has been on changes in the working class. An understanding of the issue cannot be achieved, however, unless we also consider changes in the middle class. Many middle-class occupations are rapidly approaching the situation of working-class jobs in terms of routinization, lack of control, and remuneration (cf., Rinehart, 1971; Roberts et al., 1978). To avoid the decline into the working class, many members of the middle class distinguish themselves by emphasizing middle-class symbols (Gusfield, 1967). This can be expressed through sexual values and practices, which again results in segregation between the classes (Zurcher et al., 1971).

5. Finally, we should not overstate the notion of a few separate and distinct classes, each having its own unique sexual patterns. (Kinsey et al. (1948) seemed to do this in their descriptions.) Today, it is arguable that stratification has become more complex and that there are a number of distinguishable strata within both the working and the middle class. Thus it might be that any talk of embourgeoisment or convergence between the classes will depend on exactly how many classes are thought to exist and how their distinguishing characteristics are conceptualized.

SUDDEN WEALTH, GRATIFICATION AND ATTAINMENT: DURKHEIM'S ANOMIE OF AFFLUENCE RECONSIDERED*

MARK ABRAHAMSON
University of Connecticut

American Sociological Review 1980, Vol. 45 (February):49–57

This paper discusses the effects of sudden increases in wealth, a relatively neglected aspect of Durkheim's theory of anomie. The effects are examined in a representative sample of persons who won between $500 and $100,000 in state lotteries. Following an incubation period of over one year, it is found that the magnitude of winnings are positively related to gratification permissiveness and inversely related to future aspirations. However, both of these immediate effects tend to be anomia-reducing, a finding which seems contrary to Durkheim's affluence thesis. The findings are interpreted in relation to changes in normative structures, and it is proposed that such changes alter the meaning of anomia as a personal-level indicator of a state of anomie in society.

Durkheim's theory of how individuals are integrated into society stressed the importance of temporal continuity. A "rapid alteration" of the social organization, Durkheim stated (1951: 368), "must be morbid" in its consequences. If change is sudden or dramatic, it tends to sever both the ties and the commitments which bind people to the social order (cf., Wilensky, 1961: 521–39). In other words, people are unable to establish and maintain a coherent life plan (Mannheim, 1940:56). When alterations in the social structure produce widespread disruptions, Durkheim described the resulting malintegration and normative breakdown as a state of anomie. From a social psychological position, such disruptions presumably reduce the individuals' sense of belongingness, resulting in anomia at a personal level (Srole, 1956: 709–16).

At a microlevel many of the early symbolic interactionists shared Durkheim's theoretical emphasis upon continuity. Noteworthy in this regard are Cooley's (1909) view that change-induced disruptions can become like a disease to people, and Mead's (1934) view that capacities for reflective thought and realization of the self are dependent upon gradual changes in the relationship patterns characteristic of a community or society.

Most of the contemporary research that examines temporal continuity has focused upon variables such as attempted suicides (Paykel, 1974: 134–63) and grade changes (Wildman, 1978: 34–46) as consequences of such life changes as job loss and death of loved ones. Thus, adverse life changes (as conventionally defined) have been emphasized. Durkheim appreciated the significance of adverse changes—such as the sudden loss of business fortunes—but he also stressed how anomie could result from improvements in material conditions. He warned, for example, "of the moral danger involved in every growth of prosperity" (Durkheim, 1951:254). This study, following Durkheim's improvement concerns, examines the adaptations of winners of state lotteries in order to clarify further people's reactions to sudden affluence.

Durkheim's Two Types of Anomie

In both the *Division of Labor* (1933) and in *Suicide* (1951), Durkheim regarded anomie as a normative breakdown. In the former, he traced anomie to a malintegration among the components of a society and it was primarily this view which Merton helped to popularize in two essays (Merton, 1934:537–45; 1938:672–82), the second of which presented Merton's well-known means-ends typology. In this typology he largely equated anomie with

tendencies to overemphasize either institutionalized means or culturally prescribed goals. Merton dwelled specifically upon situations in which the institutionalized means were denigrated, as epitomized by the person who cheats at solitaire.

Through the deviance research stimulated by Merton's original paradigm, further attention was directed at the problem of differential access to the legitimate means (cf., Cloward and Ohlin, 1960; Clinard, 1964). Finally, anomic conditions (i.e., blockage) were regarded as most pronounced among the poorest segments of American society. In *Suicide* (1951), Durkheim recognized the potential anomie-producing qualities of both poverty and affluence, and Merton also noted the "anomie of affluence" that can result "when Fortune smiles" (Merton, 1957:188). However, Durkheim's analysis of affluence was less emphasized by Merton, especially in his earlier essays and by the Merton-inspired applications (Mizruchi, 1967:439–46). Most overlooked was Durkheim's (1951:254) contention that poverty was "a restraint in itself" which by "compelling moderation, accustoms men to it . . . . Wealth, on the other hand . . . suggests the possibility of unlimited success." Thus, wealth deludes people into thinking that there are no limits and in the absence of normative restraints they become rebellious, immoral, and eventually, despondent.

A de-emphasis upon the anomie of affluence may be partially attributable to the time at which Merton's first essays appeared, namely, during the great depression of the 1930s (Simon and Gagnon, 1976:356–78). People's capacity for handling plentiful riches hardly presented a pressing social problem. Similarly, the general economic conditions then prevalent may also have led Merton to be sensitive to restricted opportunities. However, Simon and Gagnon (1976:356–78) argue, access to institutionalized means is not now problematical for large segments of the American population. It is the relative capacity of people to cope with potentially abundant gratifications that has correspondingly become more problematical because when access to institutionalized means of attainment is overly easy the rewards can become trivialized. By juxtaposing gratification against attainment orientations, Simon and Gagnon present a typology of adaptations that may be highly relevant in a period where relative affluence characterizes a large segment of the society.

For Durkheim, however, the anomie of affluence is a consequence not only of the distribution of wealth, but also of changes in wealth. He argued, at a societal level, that states of anomie were especially likely if an improvement in material conditions occurred rapidly. "In the case of . . . an abrupt growth of . . . wealth . . . the scale is upset; but a new scale cannot be immediately improvised" (Durkheim, 1951:253). Following Durkheim, but focusing upon social psychological correlates, this study will examine the anomia-producing effects of sudden increases in personal wealth, and the role of gratification and attainment orientations as intervening processes.

It is, of course, generally difficult to equate Durkheim's conception of anomie with any personal (i.e., individual-level) qualities. This is particularly true when the focus is upon his anomie of affluence thesis, because it contains social psychological implications that seem to be incongruent with each other.

On the one hand, Durkheim describes affluence as entailing an insufficient discipline of passions which ultimately leaves people empty-handed and weakens their desire to live. This effect may be consonant with the low sense of belongingness (or high estrangement) tapped by the Srole anomia scale (and other similar scales that purport to measure alienation, internal-external control, or the like).

On the other hand, Durkheim also views affluence as overstimulating desires by bestowing upon people a sense of power that deceives them into believing that they are answerable only to themselves. While Durkheim regards it as a false sense, such feelings of power nevertheless seem quite inconsistent with high scores on an anomia, or related, scale.

There is, in sum, ample reason to be hesitant about translating Durkheim's anomie of affluence theory directly into individual-level hypotheses. The conditions under which anomia can be viewed as a personal-level proxy for a state of anomie will be examined in the final section of this paper.

THE SAMPLE

Each year the lottery division of the Connecticut State Commission on Special Revenues provides the U.S. Internal Revenue Service with printouts of the names, addresses and social security numbers of all persons who won any amount of money during the preceding year. Also included is the amount they won, the date and the type of lottery involved. These printouts for the years 1977 and 1978, containing a total of almost 5,000 entries, were taken as the initial population.

Most persons win relatively small amounts, especially when compared with what is promised by advertisements for the lottery. However, when both 1977 and 1978 were combined, there were: 58 persons who won between $50,000 and $100,000; 26 persons who won between $21,000 and $49,000; 94 persons who won exactly $20,000; and 12 persons who won between $11,000 and $19,000. In total, there were 190 persons who won between $11,000 and $100,000, and all of them were included in the sample list. An additional 110 persons who won $10,000 or less (down to a few hundred dollars) were also included by a systematic sample of every 41st name not included among the over $10,000 winners. Thus, 300 persons were initially selected to receive mailed questionnaires. The questionnaires were anonymous, but from coding on the return envelopes each respondent was identified on the Internal Revenue Service list from which the amount and date of their winnings was ascertained and coded with the questionnaire data. (Each respondent was subsequently coded by number only, and the IRS lists were destroyed.)

As many as three separate mailings were eventually sent to each of the 300 persons initially selected. In the first and second round 19 persons were excluded either because they had died (in the interim) or moved and no forwarding address existed according to the post office records. From this revised list of 281 "eligible" persons, 164 subsequently returned (at least partially completed) questionnaires—a return rate of approximately 60%. This sample of 164 persons was then compared with the revised list of 281 eligibles. There were no significant, or substantial, differences with respect to date of winning, type of lottery, or amount of winning, though refusals exhibited a slight tendency to have won earlier (i.e., longer ago) than respondents.

Twenty-one months before this survey was conducted, a multistage probability sample of the entire state of Connecticut (n = 568) indicated that just over one-half of all adults in the state had participated in one or both of the lotteries during the preceding year (Abrahamson and Wright, 1977). In terms of occupation, sex and income they were highly representative of all state residents, but participants did tend to be slightly older. The 164 respondents included in this sample are, in all of the preceding respects, almost perfectly representative of the larger sample of lottery participants who, in turn, are generally representative of all adults in the state.

Open-ended interviews with 10 of the lottery winners provide additional background information. Half of them were in-person interviews, conducted independently of this study (Monagan, 1979:33–6). The other half were telephone interviews conducted as part of this study.

THE MEASURES

The winnings of persons in the sample, as previously noted, vary from as little as a few hundred dollars to as much as $100,000. The greater their winnings, it is hypothesized, the greater should be the anomia effects. However, the value, or marginal utility, of people's winnings may vary as a function of their prior income levels. A $75,000 prize, for example, will probably have a greater impact upon an $8,000 a year factory worker than upon a $50,000 a year executive. Therefore, winnings are operationalized in two ways: by the (log of the) amount won (cf., Hamblin, 1971:423–52), and by a ratio of the absolute amount won to preceding year's total income.

Anomia is measured by the five-item Srole (1956:709–16) scale and one item from the Neal and Seeman (1964:216–26) powerlessness scale. (Other Neal-Seeman items were also included, but they helped to identify other factors that were theoretically uninteresting.) These six items comprise a unidimensional measure according to a (varimax orthogonal) factor analysis. Items and loadings are as indicated in Table 1. Each respondent was given a composite factor score on the anomia factor, as defined above.

In order to construct composite measures of the gratification and attainment orientations discussed by Simon and Gagnon (1976:356–78), a large (and equal) number of items relating presumably to each dimension were subjected to a variety of factor analyses. Those items which greatly overlapped both dimensions were systematically removed until items relating to the two constructs were eventually distinguishable from each other. The theoretically clearest solution entailed two somewhat oblique factors (r = −.22).

The first factor, which includes the gratification items, focuses upon people's perceptions of, and their approval or disapproval of, contemporary patterns of indulgence: alcohol consumption, drug use, and sexual standards. More specifically, this factor is built on the degree to which people generally condemn what they perceive as the styles that are in vogue. This factor may be further described as involving proscriptive gratification norms or an ascetic orientation.

Table 1. The Anomia Factor

Items	Anomia Factor Loadings
(16) In spite of what some people say, the situation of the average person is getting worse, not better.	.64
(7) More and more I feel helpless in the face of what's happening in the world today.	.64
(12) These days people don't really know who they can count on.	.62
(23) It's hardly fair to bring a child into the world with the way things look for the future.	.58
(20) Nowadays, a person has to live pretty much for today and let tomorrow take care of itself.	.48
(5) Most public officials are not really interested in the problems of the average person.	.48
(Eigenvalue = 2.59; % of Var. = 43)	

The second factor focuses upon people's general commitment to strive for future attainments: to build a marriage, become wealthy, or simply excel at whatever they do. The third item, dealing with the enjoyment of wealth, appears, at face value, to be discrepant with the other items. Its inclusion requires additional interpretation. Perhaps its variation in common with the other attainment items results from respondent's subjective reaction to the question as meaning that enjoyment is natural *after* people strive to acquire wealth. This is admittedly conjecture, but such an interpretation would account for the item's inclusion in this factor. All of the items and their loadings are presented in Table 2.

By contrast to the first factor (i.e., gratifications), the second factor (i.e., attainment) stresses prescriptive rather than proscriptive norms, and a more futuristic orientation. These are, of course, two of the major characteristics attributed by Weber to the early Puritans (Weber, 1958). If Weber was correct in noting a tendency for these orientations to fuse, that would account for the preliminary difficulty encountered here in constructing separate indices of each. However, the importance of their analytic distinction from each other prompts their operational separation and it should be recalled that, as measured here, these two dimensions are only mildly related.

Single items were also included in the questionnaire to measure: total yearly income, marital and occupational status (both before winning and now), and sex and age.

RESULTS

Neither measure of the winnings variable exhibits a significant, or substantial, direct correlation with anomia (i.e., factor

scores on anomia). However, anomia is significantly related to both the denial of gratifications and future attainments factors, though neither zero-order correlation is large. A complete correlation matrix, including all of the variables, is presented in Table 3. For the most part, it contains few substantial correlations. The entire pattern becomes clearer, however, when people are dichotomized according to the time they won; that is, the time that elapsed between this survey and the time they won. After winning a large amount, most of those interviewed report experiencing a long hiatus. "It took a good year to realize what happened," one winner explained. It is after such an incubation period that the effects of winning become visible. The approximate mid-point of the time variable in the sample is one and one-half years, and this interim corresponds reasonably well with the self-reported incubation periods. (One hundred and fifty people totally completed questionnaires; 73 of them won between one and one-half and three years before the survey.) Also presented in Table 3 is the correlation matrix including only those persons who won one and one-half years, or more, before the survey.

The relationships between anomia and both gratification and attainment are more pronounced in this subsample; and both of the latter variables are also more strongly related to the winnings variables, (log) amount and ratio of winnings to prior income.

The positive relationships between both measures of winning and people's acceptance of gratification are congruent with Durkheim. He proposed that a dramatic increase in wealth would lead people to become more permissive, but an endless pursuit of pleasure, coupled with a rejection of normative restraints, was regarded as generating anomie. However, these findings indicate an inverse relationship between anomia and acceptance of gratification (r = −.30); the more indulgent the orientation the lower the anomia.

For some persons, orientations toward gratification are relatively fixed by internalized moral norms; as such, they are not responsive to changes in opportunity (cf., Campbell, 1964). In addition, the proscriptive quality of gratification norms (i.e., thou shalt not) is associated with inflexibility and pervasiveness (cf., Mizruchi and Perrucci, 1962). Little indulgence is therefore possible for a person who is striving to maintain a moral identity in a social network that supports proscriptive gratification norms; the boundaries are too inelastic and too few situations are defined as allowing for exceptions.

The roles of both internalized standards and social pressures are illustrated by the experiences of a 32-year-old married woman whose lottery ticket produced a very large winning. Just before the lottery drawing she dreamt of owning a Lincoln Continental, "the big one with the wheel on back and everything." After she won, she also began to think about going to fancy restaurants, staying in nice hotels, going on a big "shopping spree" at Tiffany's in New York.

Two years later, however, her life style

and her possesions are the same as they were before, except for a much larger savings account. "At times . . . a part of me says, 'Just do it! Break loose!' But we don't." She claims to not fully understand it, but something inside of her seems to restrain her impulses. She is aware, though, of her own and her husband's concern for appearances; that is, how they think they would look to their friends if their life style became more indulgent. "People we know wouldn't have accepted it . . . they would have thought, 'the lottery made her do it.' "

For other big winners, there is the previously described hiatus, and then an increased pursuit of gratification that is anomia-reducing. These persons are either more relaxed about indulging themselves or/and associate with others who are more permissive in this regard. In either case, they seem able to establish more subjectively satisfying modes of adaptation. The experiences of another large winner, also a woman and in circumstances similar to the first prior to winning, are instructive. She quit her job at the drug store and then took a trip, bought horses, cars, a mink coat, etc. "I can't think of anyone who is a friend who was upset or envious." She claimed that it did take her a while to get used to indulging, but "now if I get bored I go out and buy something and then I feel better."

Aspirations for future attainment, in contrast to gratification acceptance, are inversely related to the size of a person's winnings and positively related to anomia. Thus, large winnings depress strivings for the future, and the more they are not depressed, the greater the experience of anomia. It may be that a lottery windfall produces dissonance for persons with a strong attainment orientation; perhaps, for them, it is not the way people are supposed to acquire wealth. Thus, they may be estranged from meaningful commitments about which they have organized their lives. In addition, some large lottery winners became local celebrities as the result of media coverage. Becoming a public figure is often associated with new, and baffling, expectations. One winner was asked to finance a new public pool in town; another was troubled by a "messenger from God" who kept appearing at the door asking for donations; the minor automobile accident of a winner's son resulted in front page headlines in a local newspaper. All of these situations can be experienced by winners as entailing a diminished capacity to either predict or control future events, which results in stress (cf., Coleman, 1973:1–17). The subjective stress that can ensue was clearly expressed by a 55-year-old man, who, speaking for his wife as well, looked back at the last two years and said, "We've just been bothered and worried ever since we won."

From the preceding discussion it is apparent that the indirect effects of the size of winnings, notably through attainment and gratification orientations, are more important than winning's direct effect upon anomia. These effects are examined in the path model presented in Figure 1.

Winning, it will be recalled, occurred at least several months prior to the survey for all respondents. It can be viewed unambiguously as the start of the causal chain. (The ratio of winnings to preceding year's total income and the log of amount won behave similarly as independent variables, though the effects of winning ratio are somewhat stronger and this variable will be employed in the following model.) On theoretical grounds, anomia must be placed at the end of the chain. The placement of gratification prior to attainment is the most problematic decision, but it is based upon the previously discussed view of gratification acceptance as entailing internalized proscriptive norms which, as such, are more enduring personal qualities, less susceptible to situational change than prescriptive attainment norms.

The adequacy of this path model is summarized in Table 4. Based upon the ratio of Betas to their standard errors, the various paths from gratification are the most "secure." The entire model explains a modest 15% of the variance in anomia, but it is the role of gratification orientations that warrants theoretical emphasis.

The amount that people won is positively related to subsequent changes both in marital and in occupational status, but neither status change is included in the path model because neither contributes any additional source of explained variance in anomia. However, marital change is the only variable that focuses upon behavioral changes in "bondedness" and it therefore warrants attention. In addition, it helps to clarify further the impact of changes in gratification permissiveness. First, operationally, this variable is a dichotomy between any change in marital status and no change at all. The two most prevalent changes that occurred after

winning were: from married to separated or divorced, and from single to married.

Marital changes are positively related to acceptance of gratification (r = .25) and, like gratification acceptance itself, marital changes are inversely related both to future attainment (r = − .25) and to anomia (r = − .21). This observed pattern of relationship suggests that marital changes are best viewed as behavioral adjustments to more permissive gratification-inspired life styles. (Marital change was initially included in the path model after gratification and attainment on the assumption that changes in behavior occur subsequent to changes in attitude; but all of the variation it shared in common with other variables was already accounted for by gratification.)

CONCLUSIONS

The findings indicate that the major effects of the size of winnings are an increase in gratification acceptance and a decrease in future attainment orientations. These results are substantially congruent with the first part of Durkheim's anomie of affluence thesis. Also congruent is the positive, albeit small, direct path between size of winnings and anomia (if anomia is regarded as a personal-level proxy for anomie). I think this direct path reflects a weak tendency for a rapid increase in affluence, per se, to result in higher anomia; but some nonmeasured variable may intervene.

However, the larger, indirect effects of the size of winnings tend to be anomia-reducing. By spurring a more permissive orientation toward gratifications and by depressing future attainment aspirations, *larger winnings lead to lower anomia.* Thus, increased desires do not seem so brutalizing; the appetities, when whetted, do not seem to result in detachment. High anomia is, rather, the price that is paid by those who resist a readjustment in their consumatory styles. It must also be recalled that this pattern becomes increasingly characteristic as more time elapses since the person won. There is, therefore, little basis for inferring that the observed pattern represents only a temporary mode of adaptation. Thus, when anomia is interpreted as indicating anomie at an individual level, the strongest findings of this study seem to contradict the main thrust of Durkheim's anomie of affluence thesis.

In the late Victorian period which Durkheim confronted, the failure to restrain indulgent impulses may eventually have produced a sense of bondlessness and detachment; that is, anomia. However, the prudish respectability of the Victorian era is normatively very different from the contemporary ("if it feels good do it") scene. Anomia, Mizruchi suggests, may be attributable to the strain of being out of step with the larger social structure (Mizruchi, 1969:243–51); and who it is that is marching to the tune of a different drummer has changed dramatically since the Victorian period. Thus, anomia is today experienced by those persons who, in the face of sudden wealth, continue to reject permissive gratification norms.

There is, of course, one final interpretation, rendered plausible by the lack of perfect isomorphism between Durkheim's macroconception of anomie and the microlevel measurement of anomia. Specifically, from Durkheim's position, the fact that denial of permissive gratification norms is found to produce a sense of detachment might itself be indicative of a societal state of anomie. In other words, it might indicate that there is insufficient internalization of shared regulatory norms; the problem of "modern individualism" (cf., Parsons, 1964:118–53).

This interpretation suggests that, in general, anomia can be regarded as a personal-level proxy for anomie only when a society is characterized by widely shared restrictive gratification norms. In this type of (i.e., Victorian) context it is the people with indulgent orientations who are out of step, and, hence, experience anomia. The greater the number of such persons, we may propose, the more intense the societal level of anomie. However when prescriptive affirmations ("if it feels good do it") are in vogue, the number of persons who experience anomia may actually provide an inverse indicator of anomie because it is the people who maintain proscriptive regulatory norms who are now out of step.

MANUSCRIPTS FOR THE
ASA ROSE SOCIOLOGY SERIES

Manuscripts (100 to 300 typed pages) are solicited for publication in the *ASA Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Suzanne Keller, Department of Sociology, Princeton University, Princeton, NJ 08540.

INDUSTRY MARGINALITY AND FEMALE EMPLOYMENT: A NEW APPRAISAL*

WILLIAM P. BRIDGES
University of Illinois—Chicago Circle

American Sociological Review 1980, Vol. 45 (February):58–75

The postulate that women are overrepresented in marginal industries is examined by formulating six hypotheses which relate aspects of industry marginality to female employment. Data from Population and Business Censuses and other published sources are used to evaluate these hypotheses empirically for detailed industries in both the goods-producing and the service sections of the economy. The relationship between industry differences in male/female employment and occupational segregation by sex is taken into account with direct standardization techniques. The results show that women are underrepresented in capital-intensive industries but that their industrial distribution is not strongly associated with a wide range of marginality characteristics. Furthermore, some types of industries (such as durable-goods manufacturing) employ fewer than expected numbers of women, even when the average marginality of industries in those groups is taken into account.

The belief that discrimination against women results from structural factors is a central tenet of many recent labor market studies, particularly those in the tradition of institutional economics.[1] A clear statement of this principle is given by Beck et al. (1978:707), "In providing a nonindividualistic alternative for the analysis of earnings, theories of the dual economy provide structural explanations for economic differences between racial and sexual groups. Rather than interpreting group differences in earnings or poverty as due to different rates of individual 'failure' in a competitive market, the theory suggests that such group differences may be the outcome of *differential assignments* of group members within the sectoral structure of the economic order" (emphasis added).[2] In this paper, I evaluate one of the central tenets of segmented labor market theory—that women are overrepresented in marginal industries—by assessing several explicit hypotheses with detailed census data. Furthermore, the analysis takes into account the fact that occupational segregation by sex is rampant and may influence the industrial distribution of women workers. The distribution of nonwhites, a topic worthy of attention in its own right, is not analyzed here, however. This analytic separation of women from other "economic" minorities is justified by recent empirical evidence which shows that the two groups play somewhat different roles in the economy (see Villemez, 1977; Snyder and Hudis, 1976). Therefore, the goal of this paper is to explore the applicability of the theory to but one of the groups it supposedly covers.

Hypotheses

The version of the institutional or sectoral approach that I will apply here was

Support for this project was provided by the Graduate College Research Board, UICC, and the University Computer Center. Helpful comments have been received from Dick Berk, Baila Miller, Mildred Schwartz, Ross Stolzenberg, an anonymous reviewer, and especially from Wayne Villemez. As usually happens, I could not put into practice all the worthwhile suggestions which were made. An earlier version of this paper was presented to the 73rd Annual Meeting of the American Sociological Association, held at San Francisco in 1978.

[1] This collection of studies is known by a variety of different names. The more common ones are identified as studies of dual labor markets, segmented labor markets, internal labor markets, split labor markets, core and peripheral economies, etc. An early summary is provided by Gordon (1972). A discussion of their applicability to women is presented by Blau and Jusenius (1976). For a critique, see Cain (1976).

[2] A related argument is made by Bibb and Form (1977:978).

first articulated by Bluestone (1968; 1973) and has been expanded by Fusfeld (1973). They begin with the premise that industries are grouped into a high-wage, primary sector and a low-wage, secondary sector. (I will subsequently refer to this as the marginal industry theory.) Its fundamental assertion is that workers in low-wage industries are not exploited by the enterprises for which they work. Instead, the theory portrays employers, hiring low-wage labor, as middlemen who mediate the relationship of the larger system to the disadvantaged groups of workers. Thus, it is the economy as a whole which exploits certain industrial sectors by depriving them of the institutional protection which is needed to garner high profits, make costly capital investments, and regularize their labor relations by negotiating with powerful unions. The role of individual employers is simply to pass on this disadvantage to their employees so that all levels of the industry, together, must brave the chill of open competition. Bluestone (1968) is explicit about this principle when he writes, "(we) believe that individual low-wage industries, by and large, have had little success in attempting wage exploitation. The working poor are being exploited by the economy as a whole rather than by individual firms employing them."

The distinction between marginal and nonmarginal industries which appears in the dual economy literature should not be confused with the widespread classification of industries as either goods-producing or service-producing (see Fuchs, 1968:14–17). In fact, as many dual economy schemes recognize, the two types of classifications cross-cut one another and it is logically possible for "core" industries to appear in both the service (e.g., banking) and goods-producing (e.g., auto manufacturing) sections of the economy. For reasons discussed here, it is desirable to analyze goods and services sectors separately. The reader will note that, following the terminology of Clark (1951), goods-producing industries are sometimes referred to as "primary/secondary" and services as "tertiary" industries. Neither of these terms is intended to connote anything about the marginality of these groups.

Returning to the main focus, the marginal industry theory, while being only one rendition of the general institutional economic theme, is crucial for two reasons: (1) it is the foundation of further theoretical developments—primarily those which add a neo-Marxist or radical twist (see especially, O'Connor, 1973; Edwards, 1975); (2) in conjunction with the work of Averitt (1968), it has provided the underpinnings for much of the recent empirical research (e.g., see Bibb and Form, 1977; Beck et al., 1978; and Lyle and Ross, 1973). It is essential, therefore, to know how accurately it describes the division of labor by sex.

Several important decisions were made in translating this theory into hypotheses about the patterns of female employment. First, industry marginality was regarded not as a dichotomous attribute but, rather, as a continuous property which was indexed by measurements on several different variables. Bluestone et al. (1973) suggest several relevant dimensions:

> Beyond the fringes of the core economy lies a set of industries that lack almost all of the advantages found in center firms. Concentrated in agriculture, nondurable manufacturing, retail trade, and subprofessional services the peripheral industries are noted for their small firm size, labor intensity, low profits, low productivity, intensive product market competition, lack of unionization, and low wages.

To this list, Fusfeld (1973:28–33) adds the variable of geographic dispersion, arguing that an important aspect of industry dualism is for marginal industries to function as providers of essential supportive services for the core industries which (in a regional sense) are "export"-oriented. Thus, marginal industries are necessarily less geographically concentrated, because they must be present in all producing areas or regions.

In this paper, I have deliberately avoided reducing the several different dimensions of marginality to a unitary vector or, worse, dichotomy. The major benefit of this strategy is that it avoids the wholesale loss of information which occurs with these simplifications. Moreover, findings which are presented here are from the 3-digit level of industrial detail, in contrast to the cruder 2-digit classification systems used in recent studies of comparative income attainment. (See Beck et al., 1978:718–9, for an informative summary of these schemas.) Thus, applying ready-made classification schemas would entail the further sacrifice of useful data and has been rejected.

The following is a list of hypotheses which are amenable to empirical test. Each carries the implicit qualification that "other relevant factors have been controlled":

H_1: The larger the average firm size in an industry, the smaller the proportion of workers who are female.

H_2: The higher the relative level of capital investment, the smaller the proportion of workers who are female.

H_3: The higher the relative level of productivity, the smaller the proportion of workers who are female.

H_4: The higher the level of market concentration in the industry, the smaller the proportion of workers who are female.

H_5: The higher the level of geographic concentration, the smaller the proportion of workers who are female.

H_6: The higher the level of male wages in an industry, the smaller the proportion of workers who are female.

Although the participation of other economic minorities (e.g., nonwhites) is an alleged consequence of marginality and not a defining characteristic of it, the subsequent analysis adds controls for some of these variables. The rationale for these controls is that such factors may act as suppressor variables if they are negatively correlated with female employment and positively correlated with marginality. Omitting them raises the possibility that a "true" differential allocation of women to marginal industries would be underestimated. Consequently, variables measuring nonwhite participation and employment in the South are included in the subsequent regression models.[3] In addition—because of the potential for misspecification introduced by considering nonwhite participation as an exogenous variable—an alternative specification of its role is reported in the findings.

Even though wage levels are included by Bluestone et al. (1973), as a defining characteristic of industry marginality, perhaps the level of wages is better seen as an outcome of industry structure and is therefore out of place in the block of structural variables. Or—pursuing the argument in a less-extreme form—if wages must be included in this analysis, perhaps they should be included with the control variables mentioned in the previous paragraph. Although plausible, these cautionary arguments must go unheeded. The reason is that some of the variables which are defining characteristics of marginality could not be included in this analysis and the wage data are used as a proxy measure for them.

The two variables which have been omitted are level of unionization and profitability. The first is missing because reliable data at this level of industry detail are not available; while the Internal Revenue Service does report profit data by industry, these are unsatisfactory for two reasons. First, the reporting context is suspect, not only because corporations spend millions to minimize their apparent earnings to the tax collector but also because firms in different industries can spend different amounts playing this game. Second, all other statistics in this analysis have been collected on an establishment basis by the Commerce Department, but the IRS collects data on a company basis and often aggregates data from parts of firms that operate in different industries.[4]

Because direct measurement of these

---

[3] The employment of other groups of "disadvantaged" workers might also be taken into account by adding additional control variables. In results not reported here, controls for groups such as teenage males, teenage females, nonwhite females, etc., were used. The findings are barely affected by the presence of these variables and they have the disadvantage of introducing higher collinearity into the matrix of independent variables.

[4] When IRS data are used in this paper they are never used as the sole source of data for a particular variable and they have been subjected to an adjustment procedure to heighten their comparability to Business Census data.

variables is important the inclusion of wage data is a compromise strategy. However, the conclusion that the partial effect of wages is a proxy for these variables is verified by several interindustry studies which show an association between wage levels and unionization, particularly at low levels of concentration (see Fuchs, 1968; Lewis, 1963; Weiss, 1966; and Scherer, 1970) and a similar set of findings implying a link between high wages and monopoly profits (Dalton and Ford, 1977; and Scherer, 1970).

Occupation Effects

A relevant question, although one not typically addressed by those in the dual economy tradition, is how industry variability in female employment is affected by the differing occupational mixes of industries. Because of widespread occupational segregation by sex (see Gross, 1968; Williams, 1976; Oppenheimer, 1970; and Blaxall and Reagan, 1976), two industries which are identical in terms of structural variables (e.g., market concentration) might have differing proportions of female workers if one has a higher proportion of female-stereotyped occupations (e.g., lower-level white collar workers) than does the other. Furthermore, without additional knowledge, it is impossible to say whether the effect of these occupational distributions will be merely to increase the variance in proportion female by adding random error or will be to change the relationship between industry marginality and female employment through the addition of some type of correlated error.

In this paper, the influence of occupational composition is treated in the following way: Using one of the elementary identities of direct demographic standardization, I separate the aggregate percent female in an industry into two components: (1) a standardized rate or adjusted percent female, and (2) an occupational compositional effect (details provided below). This procedure enables one to assess how much the effects of industry characteristics on total female employment (the "crude rate") are due to the relative overrepresentation of women within occupational categories and how much they are due to differences in occupational composition itself.[5] To cite a simple example, industries with a large average firm size are caught in the middle of conflicting forces. On one side, larger size is indicative of less marginality and a hypothetically greater ability to acquire male labor. On the other side, larger average firm size is probably also associated with greater bureaucratization, a larger office work force, more clerical employees, and ceteris paribus, more women workers. The type of analysis proposed does allow one to judge, separately, the size and direction of each of these types of effects.

For the sake of parsimony, the industry effects which are mediated by the occupational compositional component are subsequently referred to in this paper as the effects through *femininity of occupations,* FOCC. The effects through the standardized rate of female employment will be labeled as the effects through *femininity of personnel,* FPER.

While there is a clear need to control for occupational differences when measuring industry effects, using this type of decomposition raises the question of how to interpret the effects of the industry structure variables on the separate components. Would the six hypotheses stated earlier imply relationships between the structural variables and only one of the components or would they imply relationships to both components? The position taken in this paper is that the hypothesized relationships should apply to both component variables.

Let us consider each in turn. In the case of FOCC (the femaleness of the occupational distribution), a two-part argument can be made. First, the industry structure variables do affect the relative sizes of different occupational categories in an industry (i.e., they are not just the result of tradition or the inherent nature of the product). For example, writing about the effects of one structural variable, capital intensity, Blauner (1964:168) says,

---

[5] This procedure does not permit one to examine how the effects of industry marginality vary across different occupations, a question which is beyond the scope of this analysis. Results indicating varying effects of marginality at different occupational levels would mirror Stolzenberg's finding (1975) of occupation specific differences in industry wage effects.

> [A]utomated manufacturing paradoxically increases traditional craft skill, which is applied, however, to maintenance problems rather than production work. Since automation involves a considerable increase in intricate plant machinery and technical processes, considerably more repairmen in various trades are needed to maintain this equipment.

The second half of the argument concerning FOCC is that the existence of a link between industry structure and occupational structure necessarily implies a link between industry structure and female employment levels given rampant sex-stereotyping of occupations. Nevertheless, it is important to recognize that this path of influence of industry structure on female employment depends on sex-stereotyping which reflects, at least in part, the conduct of actors outside the industry in question. That is, part of the reason that craft-work occupations are overwhelmingly male and, by implication, therefore, the industries that use them disproportionately male, has to do with the restrictive admissions policies of craft unions, differences in sex role socialization, and so on. Thus, the path of influence passing through FOCC reflects the articulation of industry marginality with societal sex-stereotyping.

It is easier to establish that structural variables should also influence the second component, FPER. As a "standardized rate," this component measures the industry's "preference" for females, net of its occupational structure. Thus, given the arguments about the need for unprotected marginal industries to employ unprotected vulnerable workers, we would expect the substitution of females within occupational categories for males, wherever possible. Thus, differences in FPER reflect industry differences in the use of females within occupation categories.

Data

The numbers of female and total employees across detailed occupation (n=441) and industry (n=235) categories were taken from the 1970 Population Census Occupation by Industry Table (Subject Report Tape PC(2)-7c). Manufacturing, mining, and construction industries were classified as primary/secondary industries and transportation, communication, utilities, wholesale trade, retail trade, finance, and services were classified as tertiary. Agricultural, household, and government employment were not included in the present analysis, nor were industries labelled "allocated" or "not specified" as these were at a different level of aggregation than the others. Of these 193 within-scope industries, 23 others (mostly in professional services) had to be excluded because of a complete absence of comparable data. The remaining 170 industries represent the basic study population, although there is some additional attrition resulting from the problem of selective missing data on certain variables. This is particularly true in the tertiary sector.

The primary source of data for independent variables used in this study was the economic censuses of 1967 and 1972 (U.S. Bureau of the Census, 1970; 1971a; 1971b; 1971c; 1972b; 1976a; 1976b; 1976c; 1976d). Because assertions of causality rest on substantive and not on temporal grounds in this paper, 1967 and 1972 are taken as representing a single time period. For industries which were outside the scope of the economic censuses, it was necessary to use alternative published data sources. However, noncensus figures were subjected to an adjustment procedure to heighten their comparability to census data. Details are available on request from the author.

The following are used as measures of the key independent variables. Coded from the 1967 economic censuses were the number of firms (with or without employees), the number of employees for the census week, value of fixed assets, new capital investment, and value added. From the 1972 economic censuses, concentration ratios were taken as the proportion of total industry sales held by the top four firms in each industry and, as an alternative measure of employer size, the presence of medium and large establish-

[a] Includes following variables: Fixed 'assets' per worker, value added per worker, average firm size, concentration ratio, regional concentration, median earnings.

[b] Includes following variables: Mining or construction dummy, durable-goods dummy in primary/secondary industries; transportation, communication, or utility dummy, wholesale trade dummy, retail trade dummy in tertiary industries.

[c] Includes following variables: Proportion males who are nonwhite; proportion employees who are in South.

ments was evaluated by coding the total number of establishments and the number of establishments with over 20 employees. From the 1970 Population Census, geographic concentration was measured by computing, across census regions, an Index of Dissimilarity between the labor force in each industry and the total civilian labor force. (Values range from 0 to 63.7.) From the same source, nonwhite males employed in each industry were taken as a proportion of total males employed; and employment in the South was measured with the ratio of employees in the South to total industry employment. To indicate relative wage levels, the median dollar earnings of male workers in the experienced civilian labor force of each industry was coded from the 1970 Population Census. Although these are earnings—and not wage—data, in the analysis included here, these data are adjusted for the percent of male workers employed 50–52 weeks per year.[6]

Methodology

As already indicated, there are three dependent variables in this analysis: the adjusted rate of femaleness, FPER; the occupational compositional effect; and the "crude rate" or total proportion female. These are represented on the right-hand side of Figure 1. An important consideration is that the third component, crude proportion female, is algebraically (and not statistically) related to the first two. That is, allowing for error components in the constituent variables, FOCC and FPER, means that there is no additional error in their sum, the crude rate. This can be represented in the following model:

---

[6] Another limitation of the wage data is that they are aggregated across all occupational levels in a particular industry. If, as Stolzenberg (1975) argues, the relative wage position of an industry varies at different occupational levels, different results might have been obtained if occupation-specific wage levels were analyzed. This procedure, however, seems inconsistent with the marginality thesis which argues that whole industries are stricken with low wages.

(1) $Y_3 = b_{Y3Y1}$ FPER + b_{Y3Y2} FOCC;
where: Y_3 = Crude proportion female, $b_{Y3Y1} = b_{Y3Y2} = 1$ = "unstandardized" coefficient of Y_3 on FOCC and FPER.

Being nonstatistical in character, they are indicated with broken lines in the diagram. A further consequence of this representation of the total proportion female as a synthetic third variable is that no direct effects of the exogenous variables on it are permitted. (It has no errors independent of FPER and FOCC.)

The payoff to this analytic strategem is that it does permit one to assess the differential contributions of marginality variables through FPER and FOCC. Thus, from the basic theorems of path analysis, the total effect (in Alwin and Hauser's [1975] sense of the term) of an exogenous variable—say, X_3 on the total proportion female—can be represented thusly:

(2) $$\text{Total effect} = p_{Y_1X_3}\,p_{Y_3Y_1} + p_{Y_2X_3}\,p_{Y_3Y_2}$$

Moreover, the size of this total effect is equal to the standardized regression coefficient of Y_3 on X_3 in the reduced-form equation.

Scores for FOCC and FPER were derived from the following computational formulas:

(3) $$\text{FPER}_k = \overset{N}{\underset{i=1}{\Sigma^k}} f_{ki}O_{.i}, \text{ and}$$

(4) $\text{FOCC} = Y_3 - \text{FPER}$;
where:

i = detailed occupational class,
k = detailed industry class,
f_{ki} = proportion female in occupational class i in industry class k,
$O_{.i}$ = proportion of workers in occupation i in standard population,
Y_3 = crude proportion female, and
N_k = number of detailed occupational classifications represented in industry k.

Of prime importance is the fact that standardization was carried out using the most detailed 3-digit census occupational classification. As an example of the sensitivity of this scheme, within the clerical category, keypunch operators are distinguished from tabulating-machine operators. Using data categorized this finely is consistent with the argument that higher levels of occupational segregation by sex appear with more disaggregated data (see Gross, 1968). As a standard population, the aggregate occupational distribution of the 170 within-scope industries was used.[7]

In the subsequent analysis, separate equations are estimated for primary/secondary (goods-producing) and tertiary (service-producing) industries. The reasons for separating the two are both substantive and technical. First, productivity levels and the role of labor in achieving high productivity may be different in services than in goods-producing sections of the economy. This may be for the reasons cited by Fuchs (1968:195–8), or it may simply be that the relatively low level of mechanization in service industries means that firm size (and the attendant specialization and scale economies accompanying it) is a more important relative input to productivity in services than in goods-production. In other words, firm size may be a better indicator of productivity in the tertiary case where it is difficult to achieve the same effects with substitution of capital for labor.

---

[7] A technical difficulty concerned adjustments to be made when all detailed occupations were not represented in a specific industry. (This was generally the case.) The occupational proportions in the standard population were recalibrated for each specific industry, with the base consisting of the sum of all those members of the standard population in occupations which actually were represented in the industry in question. This produces results which are consistent with the assumption that "missing occupations" in a specific industry have a proportion female which is equal to the obtained adjusted proportion female.

If that were not sufficient reason, a separate analysis is also required by the facts that: (1) there are differences in the completeness of coverage mentioned earlier and (2) some measures which are readily available for primary/secondary industries are almost totally unobtainable for many tertiary industries. Thus, had the two sectors not been analyzed separately, the measures of new capital investment and value added could not have been included in the analysis of the goods-producing sector. Because marginal industries may be slightly underrepresented in the goods-production sector, analyzing the two subpopulations separately does raise the issue that the effects of marginality are underestimated by sundering two groups which might have been analyzed together. Results presented here, however, indicate that this underestimation is trivial.

Another methodological concern is whether the representation of industry structure as six distinct variables in a regression equation captures the "spirit" of the notion of industry marginality. Thus, a different conceptual and methodological tack might be taken in which a single unobserved variable representing marginality is included in the model with a maximum-likelihood technique being used to estimate, simultaneously, both measurement and causal models. This strategy has been rejected because of the difficulty of specifying a priori a measurement model appropriate to these aggregate data and because of the danger of affirming the consequent by assuming the presence of a *single* unmeasured variable. That is—a central theme of this paper is: that industry marginality is likely to be multidimensional; that little is known about what the different dimensions are; and that at this stage of theoretical development more is to be learned by proceeding with a simpler mode of analysis. In any event, a preliminary principal-components analysis of the independent variables used here resulted in the emergence of three separate underlying factors.[8]

The analysis reported in the next section is complicated by the additional factor that nearly all of the ratio-independent variables were affected by considerable positive skew. This was particularly true for measures of average company size, value added per worker, fixed assets per worker, and new investment per worker. The subsequent regressions were thus carried out with the ratio-independent variables (but not the control variables: e.g., percentage males who are nonwhite) entered in log form. The consequences of this respecification of the functional form are discussed here.

A final difficulty concerns the correlation to be made in median male earnings for weeks worked per year. This was accomplished by purging the median-wage variable of the effect of percentage working 50–52 weeks per year with a preliminary regression and entering the residual in the main equation. Again, an alternative formulation was also tried and is reported on in the "Results" section.

Thus, the two equations estimated for primary/secondary industries are as follows:

$$(5)\ Y_1 = a + b_1X_1 + b_2X_2 + b_3\ln X_3 + b_4\ln X_4 + b_5\ln X_5 + b_6\ln X_6 + b_7\ln X_7 + b_8\ln X_8 + b_9X_9 + b_{10}X_{10} + e_{Y1}, \text{ and}$$

$$(6)\ Y_2 = a + b_1X_1 + b_2X_2 + b_3\ln X_3 + b_4\ln X_4 + b_5\ln X_5 + b_6\ln X_6 + b_7\ln X_7 + b_8\ln X_8 + b_9X_9 + b_{10}X_{10} + e_{Y2};$$

where:

Y_1 = FPER or adjusted proportion female,

Y_2 = FOCC or occupational compositional effect,

X_1 = 1 if mining or construction industry, 0 otherwise,

X_2 = 1 if durable-goods industry, 0 otherwise,

---

[8] When the principal-components analysis was done for the entire industry sample—i.e., ignoring the distinction between goods and service producing—only five variables could be included in the analysis. While the three significant factors account for 81% of the variance, the first factor accounts for only 38%. Restricting the analysis to goods-producing industries, where a more complete set of variables is available, confirms this result: Three factors are extracted; the first accounts for 34% of the variance and the three taken together account for 72%.

X_3 = Number of employees/number of companies (H_1),
X_4 = Fixed assets in \$1,000/number of employees (H_2),
X_5 = Value added in \$1,000/number of employees (H_3),
X_6 = Sales of top 4 firms/total industry sales (H_4),
X_7 = Dissimilarity index of industry labor force and civilian labor force across regions (H_5),
X_8 = Median male earnings purged of effects of percent working full year (H_6),
X_9 = Number of nonwhite males in industry/number of males, and
X_{10} = Number of employees in South in industry/number of employees.

For service industries, identical procedures were followed, but the variable representing value added per worker was dropped due to missing data. In addition, for both sectors, the reduced-form equation was also reestimated—using the independent variables listed earlier, but replacing the crude proportion female with a new dependent variable which consisted of the residuals of the number of females in the industry predicted from the total number of workers.[9]

Results

In Table 1, means, standard deviations, and correlations of variables used in each of the two regression models are shown. Although the need for separate analyses of goods-producing and service-producing industries has been argued on technical and substantive grounds, it can also be advocated on empirical ones. First, the slight difference in their adjusted rates of female employment bears witness to the fact that the separate analyses are not hiding a large component of difference in female employment. Second, a preliminary analysis confirms that a significant increment in explained variance results from allowing for separate slopes within subpopulations.[10]

This in mind, we now examine the results in Table 2, where regression coefficients are presented for the models estimating FPER and FOCC in primary/secondary industries. Of the six original hypotheses, only H_2—that female employment is depressed in capital intensive industries—is strongly supported. Furthermore, the regression coefficient for median male earnings is in the predicted direction for both components, although it is considerably smaller than that for fixed assets. The signs of the regression coefficients for the variables used to operationalize the other hypotheses are generally inconsistent across the two

---

[9] This was done because the marginal industry thesis is used here to make predictions about the *relative* utilization of female labor, and the dependent variables are expressed as ratios of the number of women to the total number of employees in a particular industry. Most independent variables also entered the equation in ratio form—e.g., new investment was measured as new capital spending per worker; company size was specified as number of workers per firm; percentage of workers in the South was measured as number of workers in the South divided by total industry total employment in all regions; etc. Consequently, these procedures fly in the face of some recent statistical warnings about regression of ratio variables with common terms (Schuessler, 1974; Fuguitt and Lieberson, 1974). Thus, to examine what irregularities had been introduced by the inclusion of variables with common terms, an additional specification was examined for each sector. Rather than express the dependent variable in the reduced form as a ratio, the number of women workers (the term that had formerly been in the numerator) was regressed on the number of workers (the term that had formerly been in the denominator), and the residuals of this equation were used as the new dependent variable. This procedure has the advantage of creating a dependent variable which is purged of size effects and which, therefore, is unlikely to have a spurious correlation with an independent variable in which size is the denominator. It has the disadvantage of building equations which are difficult to interpret, as the new zero-order correlations are, in reality, part correlations of ratio variables with number of females controlled for size of industry. However, the purpose of this procedure is merely to provide a point of comparison for the relative importance of variables in the initial specification and interpretations of significance levels and explained variance for this secondary model can safely be held in abeyance.

[10] The test performed here is described by Johnston (1972:198–9) and is similar to the well-known Chow test except that it isolates the sum of squares due to differential slopes from that due to differential intercepts. A significant reduction in error was obtained by allowing for differential slopes when the dependent variable was the total percent female and when it was either of the two components of that total.

components, and their sizes are relatively small.[11]

The results of this model also reveal large underrepresentations of women in mining and construction as well as in durable-goods manufacturing. An appropriate question is whether these differences occur because of the lesser "marginality" of these sectors or for some other reason. By looking at the differences between them and the comparison group, nondurable-goods manufacturing, before and after industry marginality variables are added to the equation, informative comparisons are made possible. That is, if the scarcity of women is attributable to the fact that these sectors are less marginal, there ought to be large zero-order differences (between them and the comparison group) which disappear when controls for marginality factors are added.

By adding equations (5) and (6), it is readily seen that the net differences in *total* female employment between one group and another comparison group can be obtained by adding the two unstandardized coefficients. Thus, for durable-goods manufacturing, the regression models in Table 2 indicate that the proportion of women in these industries is 13 percentage points less than that in the comparison group. In contrast, the difference *before* measures of marginality are added is actually less, about 10.6%. Thus, the numerical importance of men in the durable manufacturing sector is probably not a reflection of the lesser marginality of these industries—or the differences would have decreased with the addition of controls.

When mining and construction industries are compared to nondurable-goods manufacturing, the results are different. For this comparison, the zero-order differences are larger than those that survive the controls for marginality—27% vs. 17% as shown in Table 2. Thus, in part, the

---

[11] The usual interpretation of F-ratios is not technically justified since the industries studied were "chosen" on the basis of availability of data, not through probability techniques. In fact, the data are intended to comprise the universe of industries—not a sample of it. The reason F levels are presented is that they are, for any given equation, a linear transformation of squared-part correlations or "unique" variance explained.

Table 2. Regression Results for Primary/Secondary Industries

	Dependent Variable					
	FPER (adjusted rate)			FOCC (compositional effect)		
Variable	B	Beta	F	B	Beta	F
Mining or construction Industry	−.123	−.437	24.4	−.047	−.136	1.49
Durable-goods Industry	−.058	−.391	21.2	−.072	−.393	13.5
Log Average Firm Size	−.001	−.022	.065	.015	.200	3.24
Log Fixed Assets Per Worker	−.052	−.565	27.6	−.067	−.587	18.8
Log Value Added Per Worker	−.008	−.038	.106	.019	.069	.029
Log 4-Firm Concentration Ratio	−.004	−.043	.312	.006	.052	.287

	N = 80	R^2 = .717		N = 80	R^2 = .552	

seeming propensity of these industries (mining and construction) to hire men is associated with their lesser marginality. It must be emphasized that not all, or even the larger part, of these differences are attributable to the effects of marginality. The residual effects of mining or construction, a difference of 17 percentage points, is one of the larger effects in the model and is due to factors other than those generally used to define "core" industries.

Additional insight into these relationships can be obtained from Table 3, which decomposes the total associations (correlations) between predetermined variables and the crude proportion female into several meaningful parts. Column 1 reports the total association. In column 3, the total *effects* of prior variables are shown; these are equivalent to effects in the reduced-form equation predicting the crude proportion female. Column 2, which is the difference between columns 1 and 3, refers to unexamined correlation attributable to joint effects of independent variables. Column 4 shows the total paths between independent variables and the crude proportion female which pass through FPER (or the adjusted proportion

II. Selected Model Coefficients

$p_{Y_1 \cdot u} = .5320$

$p_{Y_2 \cdot v} = .6594$

$r_{uv} = .7742$

$p_{Y_3 Y_1} = .4644$

$p_{Y_3 Y_2} = .5751$

female), while column 5 indicates effects which are mediated by the occupational distributions of the various industries.

Of particular interest in this table are the findings for average firm size and 4-firm concentration ratio. Although the absolute values of these effects are small, the signs exhibit an interesting pattern. Both of these measures of marginality can be taken to represent the scale of operations of an industry. What these results show is that, as this scale increases, the occupational distributions of industries change in a way that tends to increase the number of female workers. At the same time, these changes have only small effects, in the opposite direction, on female employment within occupation categories. The first result upholds the earlier speculation that increased size is associated with increases in bureaucratization and the presence of female clerical workers. What is now apparent is that this tendency swamps out the extremely small countertendency for large-firm, concentrated industries to favor male workers within occupations.

Another revealing finding is that industry marginality variables which do have effects in the predicted direction on the crude proportion female—viz., capital intensity and male earnings—have the larger part of their influence through occupational structure, and not directly, on rates of female employment within jobs. This is evidence that a substantial part of the explained differences in female employment which are seemingly due to marginality factors are also susceptible to the influence of occupational sex-stereotyping, some of which certainly takes place at the societal level, not at the industrial level. In other words, much of the reason that women are underrepresented in high-paying and capital-intensive industries is their relative exclusion from the kinds of occupations (craft and/or professional?) which occur disproportionately in these industries. However, in both cases, there are smaller, reinforcing influences (in the same direction) on female employment within occupation categories in these industries, as well.

One surprising aspect of these findings is that the underrepresentation of women in mining and construction comes about mostly because of within-occupation deficits, not because of the occupational structures of these industries. The probable explanation is cultural; both of these industry groups are bastions of masculinity in the labor force and probably use men wherever feasible. Thus, in mining and construction, 6% of professionals are women, 57% of clerical workers are women, and 1% of laborers are women. The comparable percentages in manufacturing are 13, 62, and 15.

Because a number of potentially troublesome analytic decisions had to be made in carrying out this analysis, some measure of skepticism is perhaps warranted by these findings. That is—the dependent variables were expressed as a proportion; the key independent variables were specified in log form; and minority male employment was treated as an exogenous variable. Would other choices have produced more support for the marginality thesis?

The answers to these questions can be determined only by examining a number of alternative specifications of the basic model. In the interest of parsimony, comparative results will be reported only for the reduced-form equation. As mentioned above, an alternative to specifying the dependent variable in ratio form is to express it as a residual from the equation which predicts—from the total number of employees—the number of employed females. When this is done, average firm size and value added per worker shift from small-positive to small-negative effects; but these changes are counterbalanced by increased positive effects for the two concentration measures and by a substantially weakened effect for capital intensity.[12]

Additional comparisons can be made for models with modified independent variables, such as one which specifies pay levels by the concurrent use of median male earnings and proportion working full year as independent regressors. This change slightly enhances the negative effects on female employment of high male earnings, relative to other variables in the model, but their net effects are unchanged.[13] Alternative measures of employer size and capital intensity are available and these can also be used to verify the results. When proportion of medium and large establishments is substituted for average firm size, very little is changed. This measure of employer size has slightly greater *positive* effects on female employment than average firm size, but the other effects are undisturbed.[14] Returning average firm size to the equation shows new investment to be a somewhat less direct indicator of capital intensity, as it has slightly smaller relative effects than did fixed assets. Again, the effects of the remaining variables are unchanged.[15]

---

[12] The standardized regression coefficients in this equation are as follows (controlling for industry type, proportion of males nonwhite, and proportion of employment in South): 4-firm concentration ratio = .035; regional concentration = .148; average firm size = −.032; value added per worker = −.116; median male earnings (adjusted) = −.085; fixed assets per worker = −.142.

One additional bit of tinkering with the independent variables in this model involves entering measures of marginality in "pure" rather than "log" form. The results of this are similar to those of specifying the dependent variable as a residualized variable. The proportion of variance explained by the total model drops to .49; the relative importance of capital intensity is diminished; and the effects of average firm size and value added per worker change from small-positive to small-negative values.[16] These changes seem to result from the decreased zero-order correlation between the nonlog version of fixed assets per worker and proportion of employees who are female (−.56 to −.38). A plausible explanation of this drop is that, when the dependent variable is expressed as a proportion, additional increases in male employment with increasing capital intensity are subject to ceiling effects so that the curvilinear form is a better functional fit.

Finally, to guard against the possibility of a drastic error in model specification, a model was constructed in which the proportion of males who are nonwhite was treated as an endogenous variable and reciprocal causation between this variable and percent female was allowed. An additional independent variable—median years of schooling of male employees—was added to the model, to assist in identification of the model. That is, low educational attainments (as a proxy for requirements) were assumed to contribute to the percentage of nonwhites employed, though not to the percentage of females employed. (In 1973, the median years of school completed for white males was 12.4, for *all* females was 12.2, and for black males was 10.3.) The results support exactly the same conclusions as the results presented in Table 2.[17]

---

[13] The standardized regression coefficients in this equation are as follows: 4-firm concentration ratio = .009; regional concentration = .089; average firm size = .105; value added per worker = .029; median male earnings = −.295; proportion working full year = .194; fixed assets per worker = −.602. Some would argue that another *defining* characteristic of marginal industries is their propensity to provide unstable employment and that the "weeks worked" variable also should be entered in the model. There are two difficulties with this. First, doing so muddies the waters conceptually, insofar as employment instability generally is taken as a characteristic of secondary labor markets which are analytically distinct from peripheral or marginality industry structures. The second difficulty is that its effects are positive on female employment. The higher the proportion of men who work full year in the industry, the more likely women are to be employed there.

[14] The standardized regression coefficients in this equation are as follows: 4-firm concentration ratio = .004; regional concentration = .106; proportion medium and large establishments = .167; value added per worker = .016; median male earnings (adj. for percent working full year) = −.135; fixed assets per worker = −.616. As is the case in the model reported in footnote 11, controls were present for mining and construction, durable-goods manufacturing, proportion of employment in the South, and proportion of male employees who are nonwhite.

[15] Here the standardized regression coefficients are as follows: 4-firm concentration ratio = .049; regional concentration = .090; average firm size = .078; value added per worker = −.139; median male earnings = −.130; new capital investment per worker = −.491. The negative effects of value added per worker seem to be a direct consequence of the weaker effects of capital intensity.

[16] The standardized regression coefficients for the variables of interest are as follows: 4-firm concentration ratio = .060; regional concentration = .125; average firm size = −.084; value added per worker = −.160; median male earnings = −.151; fixed assets = −.283.

[17] The standardized regression coefficients for the complete structural form for females were as follows: 4-firm concentration ratio = .009; regional concentration = .107; average firm size = .076; value added per worker = .008; median male earnings =

	N = 56	R^2 = .386		N = 56	R^2 = .392	

While further methodological manipulations are possible—e.g., changing to a residualized dependent variable and nonlog independent variables at the same time—the point of diminishing returns has certainly been reached, if not crossed. The preponderance of evidence shows high levels of fixed assets to have a strongly depressive effect on female employment in these sectors and shows high male earnings to have a mildly inhibiting influence in the same direction. However, more sweeping assertions about the relation of female employment to a broad range of marginality characteristics are definitely unsupported. In particular, the variables that measure the scale of operations of an industry—the number of workers per firm, market concentration, and geographic centralization—are only trivially related to total female employment in the predicted direction. In short, for goods-producing industries, the marginality thesis is only a partial truth. What seems especially misrepresentative about the use of "marginality" as a metaphor is the vision it conjures of female employers: petty capitalists tucked away in the nooks and crannies of the industrial structure and—due to the constant pressures of unrestrained competition, merely eking out a living.

As often noted, service industries, particularly those in the trade and service sectors, are higher on most dimensions of marginality than manufacturing industries. However, because there is a lot of internal variability in this sector (its gamut includes department stores and shoe repair shops, electric utilities and dairy stores), the key question is whether differences in industry marginality are associated with differences in the proportion of employees who are women.

Table 4 provides the information needed to examine five of the six hypotheses that have been proposed in the introduction. The relationship between value-added and female employment in tertiary industries cannot be investigated because of inadequate data.

−.216; fixed assets per worker = −.580; percent males who are minority = −.226; mining or construction industry = −.307; and durable-goods industry = −.412.

The comparable coefficients for the structural form predicting nonwhite male employment were: 4-firm concentration ratio = .011; regional concentration = −.120; average firm size = .008; value added per worker = .198; median male earnings = .232; fixed assets per worker = −.058; proportion of workers who are female = −.002; proportion of workers in South = .258; median years of education for males = −.761 and mining or construction industry = −.44.

As can be seen, the equation for nonwhite male employment was identified by excluding the durable-goods manufacturing variable and the equation for female employment was identified (in fact, overidentified) by excluding median years of education and proportion of workers in the South. It is interesting that, when nonwhite and female employment are allowed to be simultaneously determined, industries employing nonwhites also fail to fit the marginality stereotype.

What is apparent is that there is even less support for the marginality theory in this sector than in goods-producing industries. Hypothesis H_1 is completely controverted by the finding that increases in the number of employees per firm lead to increases in the adjusted proportion of women employed in an industry and to large increases in the "femininity" of the occupational composition of these industries. Regional concentration has consistently negative effects on the proportion of females employed, lending some support to H_5; but the effects are rather small. The other three marginality variables have effects whose signs are inconsistent across the two component variables and, with the exception of the effect of log-fixed assets on the adjusted proportion female, effects which are quantitatively minute.

The dummy variables for wholesale trade (and for transportation, communication, and utilities) have large negative effects, particularly on the occupational-composition component. For wholesale trade, the unstandardized effect in the reduced form is −.121 plus −.150 or −.271 (the excluded category is finance and services) which exceeds the zero-order difference of −.189. For transportation, communication, and utilities, the partial effect is −.279 which is larger than the zero-order effect of −.169. In essence, these comparisons indicate that, if these industries were further from the "core" in terms of firm size, etc., they would have even fewer female employees than is now the case.

As in goods-producing industries, the effects of these different aspects of marginality can be separated into their components. Thus, industries with larger average firm sizes employ higher proportions of women workers, an increase which primarily results from the differences in the occupational structure of large-firm industries (see Table 5). Another interesting sidelight to this analysis is that industries with high levels of fixed assets, with relatively high male earnings, and with high product-market concentration, all have fewer women workers than would be expected after adjustments are made for their occupational distributions, but that their occupational distributions tend to favor female workers. With the exception of industries with high levels of assets, these tendencies tend to cancel one another. There are also consistent tendencies for geographically centralized tertiary industries to employ fewer women.

As with goods-producing industries, these results must be evaluated against several threats to their validity. The two respecifications which have the greatest

	$r_{uv} = .7607$				

potential for upsetting the findings—i.e., changing the dependent variable to a residualized variable and entering the independent variables in nonlog form—produce even less support for the marginality thesis. When the residualized dependent variable is used, the moderately negative effect of fixed assets becomes positive, and when independent variables are entered in "raw" form, the effect of industry concentration becomes substantially positive. Thus, the results presented in the preceding tables, compared to those emerging from alternative model specifications, are ones that tend to case the marginal industry thesis in a relatively favorable light, dim as it may be.

Finally, let us consider the possibility that the findings would change if primary/secondary industries and tertiary industries were analyzed together. In a separate regression analysis where this change was made, the results confirm the previous conclusions. Having a large average firm size is moderately *positively* correlated with the employment of women (primarily through changes in occupational structure) and high levels of fixed assets are strongly negatively associated with female employment. Low-wage industries have slightly depressed levels of female employment and there is essentially no relation between female employment and economic or regional concentration.

Summary and Conclusions

A total of six hypotheses relating female employment to industry marginality have been examined with strong support emerging for one—women are less likely to be employed in primary and secondary industries with high levels of fixed assets per worker. There are slight tendencies for women to be underrepresented in primary/secondary industries where males have high earnings and in tertiary industries that are regionally concentrated or capital intensive. These results are important because they are found at a more refined level of aggregation than is typical of studies of this type and because they take into account the occupational structuring of the industries in question.

Along these lines, it is significant that the effects of marginality characteristics on the proportion female in an industry are often transmitted by the occupational structure. In some instances, such as in the relationship between average firm size and the "femaleness" of the occupational structure, the direction of the effect is opposite to the prediction made by the marginal-industry thesis. In others, the direction is consistent with the hypothesis, such as the deficit in female employment which corresponds to the occupational structuring of capital-intensive industries. In theory, therefore, a large component of this industrial patterning of employment by sex is susceptible to changes in the level of occupational segregation by sex. What this study indicates, though, is that a completely egalitarian occupational structure would have a mixed impact on women workers. On balance, they would enjoy gains by entering capital intensive industries in greater numbers; but they would encounter some industrial level setbacks as they would become more heavily represented in small-firm industries in the tertiary sector.

The finding that certain types of industries pose major barriers to female employment merits further attention. This is particularly true because these differences persist after controls for industry marginality have been made. That is—the continued relative shortage of women in wholesale trade; transportation, communication, and utilities; durable-goods manufacturing; and mining and construction is not because these industries are less marginal but for some other reason. For the first three groups in this list, the influx of women would be enhanced by more egalitarian occupational opportunities. However, in the case of mining and construction, the major part of the relative absence of women workers is not explained by the "maleness" of the occupational distribution but by their systematic exclusion across all job levels—perhaps through some combination of tradition and present discrimination.

In conclusion, two separate explanations can be offered for the failure of most measures of industry marginality to predict levels of female employment. One is that, in the economy, women do not play the role which is attributed to them by the theory of marginality—i.e., being a readily available group whom "core" employers regard as second best, and who are passed over in hiring by those with the resources to get their first choice, prime-age males. Instead, these findings depict a different portrait of women in the economy—a group who are as likely as men to be employed by the industrial "elite." And while goods-producing industries do vary in the extent to which they employ women, these variations reflect factors unrelated to an industry's marginality in the economy. Furthermore, in service industries, there is some evidence that powerful industries, as indicated by large and average firm sizes, choose women before men. In other words, if we accept a queue theory of employment, we can infer that, for service employers, women have some positive qualities that place them ahead of men in the line.

The second explanation suggests that there are different types of marginal industries and that there are different groups (segments) in the labor force "assigned to" each. According to this alternative, women might be described as that part of the secondary labor force which is suitable for industries which are high on the labor-intensive dimension of marginality. Or, more speculatively, it might be argued that nonwhites are the part of the secondary labor force which is allocated to industries which are marginal in the sense of being unconcentrated and decentralized. Note that this alternative is less thoroughgoing than some others, in that it does not require one to abandon basic premises about women as employees and about employers' beliefs concerning women as employees. That is—women can still be regarded as a second-best group; but we change our thinking about whom they are second-best "for" by complicating our definition of industry marginality.

While each of these alternatives suggests areas for additional research, both require new empirical *and* theoretical initiatives. Thus, it is unlikely that more powerful conclusions about the industrial role of women will emerge until we stop charging our theoretical batteries with the weak current of "core" and "periphery."

THE FLEMISH MOVEMENT IN BELGIUM AFTER WORLD WAR II: A DYNAMIC ANALYSIS*

FRANÇOIS NIELSEN
University of Chicago

American Sociological Review 1980, Vol. 45 (February):76–94

This paper argues that two theoretical perspectives which have been used to explain resurgences of ethnic solidarity in modern societies, the *reactive ethnicity* model and theories of solidarity based on mechanisms of *competition* between groups for resources, are based on sets of incompatible assumptions and lead to opposite predictions with respect to the social circumstances under which ethnic resurgences occur in modern societies. Predictions of the reactive ethnicity and competition theories are tested by using as an indicator of ethnic solidarity the vote for the Flemish movement in Belgium after World War II, measured at the canton level. Hypotheses about the social bases of support for the Flemish movement are incorporated into a dynamic model of political mobilization represented by linear differential equations. The differential equations model is estimated using a pooling of cross-section and time-series data technique which is designed to correct for both the autocorrelation of disturbances and heteroscedasticity. Results with respect to the social bases of support for the Flemish movement reveal positive effects on ethnic solidarity of income and employment in the tertiary sector, no effect of employment in the primary sector, and a negative effect of industrialization. Overall, the empirical analysis lends support to the competition theories of solidarity and disconfirms the reactive ethnicity model. The dynamic nature of the mobilization process is also found to differ systematically across parties.

1. INTRODUCTION

In much of the sociological literature, the fate of ethnic and other ascriptive distinctions based on caste, race or religion is viewed as one of ultimate dissolution in modern societies. Systems of social organization based on ethnic distinctions, it is said, correspond to a relatively primitive level of development and are poorly adapted to the requirements of modernity. Therefore, they are doomed to be replaced by more adequate institutions during the modernization process. Both the functionalist and Marxist traditions agree with this prediction.

The functionalist argument, outlined by Lipset and Rokkan (1967:1–64), has also been labelled the *diffusionist* (Hechter, 1975) or *developmental* (Ragin, 1977) perspective. The functionalist model assumes that elements of the modernization process such as the spread of a market economy and bureaucratization entail the precedence of universalistic criteria that cut across ascribed statuses such as ethnicity. With modernization, the salience of ethnicity as a factor of the system of stratification and political cleavages is progressively eroded. Ethnic distinctions are superseded by more functional distinctions and integration mechanisms. This position is quite typical of the social change literature (Berger, 1971).

Marx's (1964) scheme of the historical evolution of capitalist societies implies similar predictions. Ethnic cleavages are particularly salient in a system of communal property, an early stage of economic organization (Marx, 1964:69). In the communal property system, the main factor of production is land collectively owned by the community, and tribal or

I am grateful to Michael Hannan, Rachel Rosenfeld, Jacques Delacroix, Charles Ragin and an anonymous reviewer for useful comments on earlier versions of the materials presented in this paper. The opinions presented here are the sole responsibility of the author. An earlier version of this article was read at the 9th World Congress of Sociology in Uppsala, Sweden, August, 1978. The development of the estimation algorithm and collection of the data were helped by several institutions and individuals: NSF grant GS-32065, NIE contract 74-0123, Michael Aiken, Pierre Lenain, Pat Barchas, Mark Van Naelten, the Belgian Archives for the Social Sciences, the Consulate General of Belgium in San Francisco and the Ministry of the Interior.

ethnic loyalty is therefore an essential precondition of production. The rise of capitalism implies the progressive separation of the factors of production (land, labor, capital) and decreases the importance of community membership as a precondition. Capitalism also entails a progressive polarization of individuals into two classes defined with respect to the ownership of the means of production which irons out traditional cleavages based on ethnicity. Therefore, the salience of ethnic distinctions should decrease with modernization according to the Marxist model.

Both the functionalist and Marxist arguments predict that the salience of ethnic distinctions decreases with modernization.[1] Researchers writing outside the functionalist and Marxist traditions, such as Park (1950), often accept this view. Park's optimistic description of the race relations cycle suggests that ethnic boundaries ultimately disappear in all situations of permanent contact between groups. However, such predictions do not agree with the empirical evidence of resurgences of ethnicity in such advanced countries as Canada, Great Britain, France, Yugoslavia and Belgium. The implications of several influential theories are clearly unacceptable in view of the historical evidence.

The purpose of this paper is to investigate conditions under which there can be a resurgence of ethnic solidarity in modern states. In Section 2, I contrast the basic assumption of two classes of theories which predict such resurgences: the *reactive ethnicity* model proposed by Hechter (1975) and the *competition* theories of ethnic solidarity developed by several writers in a variety of substantive contexts (see the references in Section 2). In Section 3, I outline the history of the Flemish movement in Belgium and argue for the usefulness of that example for my purpose. Section 4 is devoted to a discussion of the methods with which electoral indicators of the success of the Flemish movement after World War II are analyzed. In that section, I propose a dynamic model of the rise of Flemish solidarity. Empirical estimates of the coefficients of the dynamic model are presented and discussed in Section 5. Finally, Section 6 is devoted to concluding remarks concerning the most important results of the analysis.

2. THEORIES OF ETHNIC SOLIDARITY

a. Reactive Ethnicity

Hechter (1975) proposes explaining the persistence of ethnic solidarity in modern societies within the framework of the reactive ethnicity model. He views resurgences of ethnic solidarity as reactions of the culturally distinct periphery against exploitation by the center. Reactive ethnic solidarity occurs in a modern setting when there is a cultural division of labor, or pattern of structural discrimination. Structural discrimination occurs (Hechter, 1974:1154) "when individuals are assigned to specific types of occupations and other social roles on the basis of observable cultural traits or markers. . . ." With cultural division of labor, ethnic boundaries tend to coincide with lines of structural differentiation, and collective action based on ethnic boundaries (ethnic solidarity) ensues. Structural discrimination (and ethnic solidarity, as a result) can exist regardless of the level of structural differentiation in the society as a whole.

Hechter (1974; 1975) argues furthermore that one of the major mechanisms leading to a cultural division of labor is internal colonialism. Modernization does not affect the population circumscribed by national boundaries evenly. Instead, modernization spreads from one or several centers towards the periphery. The center controls development in the periphery in such a way that the population in the periphery engages in activities which are the most complementary and profitable in terms of the requirements of the center and the least rewarding economically for the periphery. Whenever populations of the center and the periphery can be distinguished by cultural markers, mobilization of solidarity on ethnic lines is likely to occur.

---

[1] See Dahrendorf (1969) for an attempt to synthesize functionalist and Marxist perspectives with respect to collective action. For Dahrendorf, the boundaries of conflict groups coincide with lines of differentiation in a functionally determined authority structure. If one accepts Dahrendorf's assumption, both the functionalist and Marxist arguments may be roughly summarized as follows: Since the criterion of ethnicity is not functionally relevant for the allocation of authority in industrial societies, the likelihood that conflict is based on ethnic boundaries decreases with modernization.

It is necessary to distinguish carefully between the internal colonialism and cultural division of labor arguments in Hechter's (1974; 1975) reactive ethnicity model. The internal colonialism argument is the description of a historical scenario leading to a situation in which ethnic boundaries and occupational cleavages coincide. The cultural division of labor argument provides the mechanism by which this coincidence of ethnic and occupational lines is translated into status group solidarity. As noted by Ragin (1976), the cultural division of labor model and the functionalist model (Lipset and Rokkan, 1967:1–64; Lipset, 1960) are identical: a group is more likely to express solidarity, or become mobilized, when several of the cleavages that distinguish it from the rest of society coincide. Such a reasoning, in the functionalist tradition, is best illustrated by Smelser's (1969:52) discussion of the conditions under which ethnic solidarity emerges in developing nations:

> The important structural feature of such an arrangement is that economic, political and racial-ethnic membership *coincide* with each other. Thus, any kind of conflict is likely to assume racial overtones and arouse the more diffuse loyalties and prejudices of the warring parties. (emphasis his)

Within the functionalist perspective, ethnic solidarity is the result of an accidental coincidence of ethnic boundaries with functional lines of differentiation. The reactive ethnicity model assumes that such coincidence is the result of a much more permanent type of arrangement: functional and ethnic cleavages coincide in situations of internal colonialism in which the center is able to keep the periphery in an economically subordinate position.

Hechter (1975:316) tests the reactive ethnicity model using electoral and census data for British counties. He measures ethnic solidarity as: ". . . the extent to which objective cultural distinctions account for the aggregate voting behavior of groups." More specifically, he utilizes as an indicator of solidarity the coefficient of determination (R^2) of the regression of Conservative voting on cultural residuals. These are the religious and linguistic nonconformity of counties purged of the effects of structural variables, such as population growth, urbanization and the proportions of the labor force in various occupational categories. He shows that the coefficient of determination associated with the cultural residuals remains high for the eight elections from 1885 to 1966 and argues that this evidence supports the predictions of the reactive ethnicity model, as opposed to the functionalist model. However, Hechter's (1975) research is plagued by a series of conceptual and analytical mistakes (Ragin, 1976; 1977).

First, Ragin (1977) has shown that Hechter's results do not hold when vote for Labour, instead of Conservative vote, is used as the basis of the measure of ethnic solidarity. For four elections from 1924 to 1966, Labour voting is practically unrelated to the cultural residuals. These results cast extreme doubts on Hechter's indirect measure of solidarity. This might have been expected given the fact that the measure of solidarity is so remotely connected with a direct measure of the participation of members of an ethnic group in a collective movement explicitly dedicated to the implementation of goals defined on ethnic lines as opposed to other cleavages.

Second, one of the major assumptions of the reactive ethnicity model is that an ethnic group is more likely to be solidary when it is disadvantaged vis-à-vis the rest of society. Such an assumption is necessary to establish a link between a situation of cultural division of labor and reactive ethnicity. Hechter (1975:43), for example, argues: "The greater the economic inequalities between collectivities, the greater the probability that the less advantaged collectivity will be status solidary, and hence, will resist political integration." There is no evidence in Hechter's (1975) book to demonstrate such a connection between relative disadvantage of the members of a group and ethnic solidarity.

Overall, therefore, there is very little empirical evidence for the usefulness of the reactive ethnicity model. However, this model does provide an explanation for resurgences of ethnicity in modern societies.

b. Competition Theories

Writers such as Deutsch (1953), Lieberson (1961), Harris (1964), Van den Berghe (1967), Barth (1969), Bonacich (1972) and Hannan (1979) have proposed theories of ethnic solidarity which involve, explicitly or not, mechanisms of competition between groups for resources. Implications of these theories and of the reactive ethnicity model with respect to resurgences of ethnic solidarity in modern societies are quite opposite. Space limitations do not permit me to present a detailed analysis of all these theories. Therefore, I focus on the version of the competition argument proposed by Barth (1969). (See Nielsen, 1978a, for a more complete discussion.)

Barth (1969) examines the conditions of stability of a polyethnic system. He argues that a system of ethnic relations is stable when the groups occupy distinct niches, or sectors of activity. Such a situation occurs when the groups engage in different types of productive activities. Coresidence is possible and is characterized by low interdependence and limited interactions between groups. Another stable situation is when the groups engage in the same activities but monopolize distinct territories. Conflict is then limited to border politics. Finally, the groups may occupy different and complementary niches. Such a cultural division of labor entails close interdependence and symbiosis, with low intensities of ethnic solidarity and conflict.

Unstable situations of ethnic contact are characterized by the fact that two or more groups compete, at least in part, for the same niche. Then, either one of the groups displaces the other or complementarity is increased by the restriction of group activities to distinct sectors. Situations of competition between groups correspond to high levels of solidarity and conflict. Note that the situations Barth (1969) considers to be stable are also the ones characterized by a cultural division of labor in Hechter's (1975) terminology. Barth (1969) predicts a low level of solidarity in such cases; Hechter (1975) predicts a high level of solidarity. The central mechanism of solidarity and conflict is therefore quite different.[2]

Barth's (1969) competition model suggests that the intensity of solidarity and conflict may increase with modernization. As modernization affects distinct ethnic groups in a traditionally stable system more homogeneously, assignments of individuals to occupations tend to be made increasingly on the basis of rational and achieved criteria that cross-cut ethnic boundaries. Members of different groups compete for the same occupations and value the same rewards. Niche boundaries and ethnic boundaries cease to coincide. The system of ethnic relations becomes unstable and the competitive tensions are manifested by a heightening of solidarity within groups and conflict between groups.[3]

Therefore, both the reactive ethnicity model and competition theories provide explanations of resurgences of ethnic solidarity and antagonism in developed societies. However, they associate such resurgences with very different structural arrangements. For the reactive ethnicity model, solidarity occurs when modernization produces a cultural division of labor in which a peripheral ethnic group is disadvantaged and exploited by the core. The competition theories associate solidarity with situations in which development diffuses more homogeneously over the national territory, the cultural division of labor breaks down and the distributions of occupations, rewards and social roles in the core and the periphery become more similar. I present a preliminary test of these conflicting hypotheses in Section 5 using Belgian data.

---

[2] Hechter (1975:37–8) cites Barth (1969) to support his discussion of the cultural division of labor model. I believe, however, that Hechter misinterprets the main thrust of Barth's argument. Hechter's confusion is rooted in the vagueness of his conceptual definition of ethnic solidarity.

[3] Harris (1964) and Van den Berghe (1967) also propose explanations of ethnic antagonism based on a breakdown of the cultural division of labor. Despite differences in their terminologies, competition mechanisms are crucial in both Harris's comparison of ethnic relations in Brazil and the United States and Van den Berghe's description of the paternalistic and competitive types of race relations.

3. THE CASE OF BELGIUM

In Section 2, I criticized the indirect nature of Hechter's (1975) measure of ethnic solidarity. (See also Ragin, 1977.) It seems that a satisfactory measure of solidarity should incorporate at least the following two concepts:

(1) the formulation of specific goals or claims defined on the membership of an ethnic group as opposed to, or in contradistinction with, other groups (such as social classes) in the social system; and
(2) a measure of the ideological and organizational mobilization of the group membership for the implementation of these specific claims.

The rise of the Flemish movement in Belgium is one historical instance in which such a direct measure of ethnic solidarity is available. The empirical analysis I propose in the next sections utilizes as an indicator of solidarity the electoral support for the Flemish nationalist parties (mostly the Volksunie) in the Flemish region of Belgium after World War II. The vote for the Flemish movement measures ethnic solidarity directly as the success of mobilization based on ethnic boundaries, as opposed to other types of cleavages. The remainder of this section is devoted to a brief historical outline of the rise of the Flemish movement.[4]

Since its independence in 1830, the political life of Belgium had been dominated by the Catholic/Secular cleavage, as in many western European countries. Conflicting views about the respective roles of the Church and the State led to the creation of two main parties: Catholic and Liberal. Industrialization and the implementation of universal male suffrage in 1919 precipitated the success of the "Parti Ouvrier Belge" (Belgian Workers' Party), later to become the Socialist party. The three parties dominated the electoral scene from the end of World War I to the early sixties. The Catholic party was powerful principally in the northern, Flemish-speaking and more rural areas. The Socialist stronghold coincided with the southern, early-industrialized and French-speaking part of the country.

As early as 1919, however, the legislative elections witnessed the first modest success of an explicitly ethnic party: the "Frontpartij." Its objective was to obtain cultural equality for the Flemish language in a Belgian society that was still heavily dominated by the French culture of the national elites in Brussels and of the state bureaucracy. The success of the Flemish movement under various party names grew continuously during the interwar period (with a small setback in 1932) to reach a maximum of 8.27% of the country's total vote in 1939[5] (De Smet et al., 1958). The movement was greatly diminished in the immediate post-World War II period due to some measure of collaboration of its leaders with the German occupants. It did not contest the elections in 1946 and 1950, and obtained only 3.59% of the vote in the Flemish constituencies in 1949 (2.06% of the national vote). With the creation of the "Christelijke Vlaamse Volksunie" (usually shortened to "Volksunie," or VU), the electoral support of Flemish nationalism resumed its steady prewar growth through every legislative election since 1958 to reach 18.8% in 1971 in the Flemish cantons (Hill, 1974).

---

[4] I do not attempt here to provide a detailed analysis of Belgian politics. An illuminating commentary is the one by Lorwin (1966). More recent treatments may be found in Heisler (1974) and Hill (1974). The last paper also contains an extensive bibliography and a review of the few attempts to analyze quantitatively Belgian political behavior, including a reanalysis of the data collected by Delruelle et al. (1970) in a 1968 survey. Finally, Zolberg's (1974) discussion of the origins of the linguistic conflict may be the most perceptive and illuminating statement available on this subject.

[5] When measured as a fraction of the vote in the Flemish constituencies, however, the Nationalist vote in 1939 corresponds to 15.05% of the electorate. The steady growth of the movement between the wars is quite impressive, although many commentators seem to have a tendency to minimize the importance of this phenomenon in view of post-World War II events.

The success of the ethnic-linguistic line of cleavage at a time when the regions of the country were becoming increasingly homogeneous with respect to social and economic structure has puzzled many observers. For example, Hill (1974:46) declares:

> . . . there is a paradox in this success. In former times, when the inequities suffered by the Flemish population were inestimably greater than in the period since the end of the Second World War, the electoral support of the Flemish nationalist parties was smaller. Furthermore, the period since the fulfillment of most of the formal demands of the movement in 1963 has seen major growth of the postwar Flemish nationalist party (VU).

Paradoxical or not, the growth of electoral support for the Flemish movement after World War II constitutes a clear instance of the resurgence of ethnic solidarity in a modern, industrialized society. The rise of Flemish solidarity is depicted in more details in Figure 1.

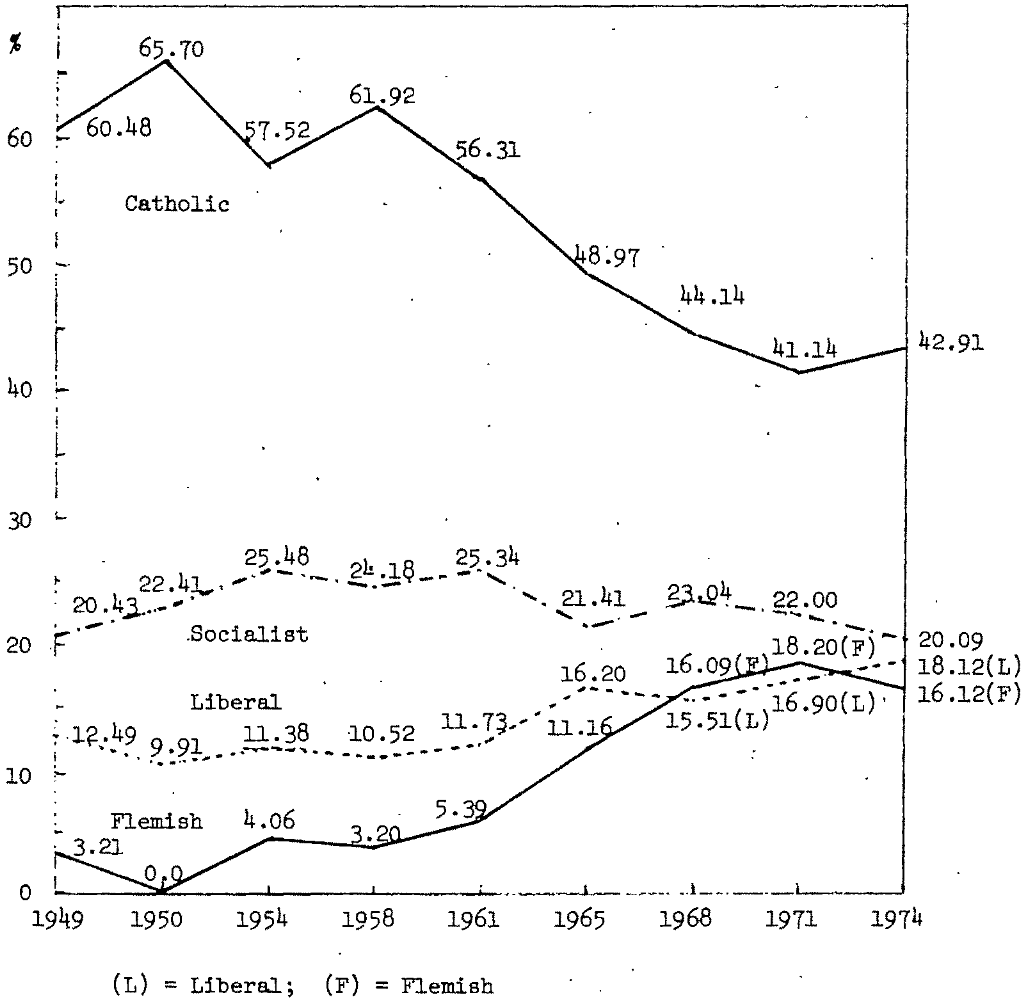

Figure 1. Evolution of support for the four major parties in Flemish cantons: 1949 to 1974. (Unweighted averages of canton percentages. N = 102.)

Figure 1 summarizes the evolution of support for the four major parties in the Flemish region during the nine elections from 1949 to 1974. The percentages of Figure 1 correspond to unweighted averages of support (in percent) for the four parties over 102 cantons (districts) of the Flemish region. The 102 cantons were selected on the basis of ethnic homogeneity (a very large majority of Flemish speakers).[6] I use unweighted averages of support because the canton is the unit of analysis in the model of mobilization estimated in Section 5.[7] Salient features of the figure are the continued dominance, but steady decline, of the Catholic party during the period (from 65.70% in 1950 to 42.91% in 1974) and the corresponding gain in support of the Flemish movement (from 0% in 1950 to 16.12% in 1974). Support for the Socialist party remains relatively constant during the period while Liberal support increases somewhat. The curves of Figure 1 provide a striking depiction of one instance of resurgence of ethnic solidarity in an advanced industrial society.

The curves depicting the evolution of supports for the Catholic party and the Flemish movement are almost mirror images of each other. This symmetry might suggest that the growth in support for the Flemish movement is the result of a simple transfer of votes from the Catholic party. The aggregate transfer might be viewed as produced by individual voters switching their preference or, more realistically over a twenty-year period, as produced in part by the failure of the older generations of voters to reproduce the same intensity of Catholic loyalty among younger cohorts reaching voting age. If the transfer hypothesis is true, the question arises whether Catholic voting is not an alternative avenue for the expression of ethnic feelings, so that the significance of the entire historical episode might be dismissed as the mere relabelling of ethnic solidarity over time. Then, a proper measure of solidarity should combine the votes for both the Catholic and Flemish parties.[8]

This is a serious issue since there is indeed evidence that Catholic voting did represent at one time a sectionalist response (in Hechter's 1975 terminology) for the Flemish electorate. First, most observers of Belgian politics agree that Catholic support included much that was generated by ethnic and regional feelings rather than the purely religious appeal of the party (e.g., Roy, 1968; Hill, 1974). Second, there is the traditional dominance of the Catholics in Flanders as contrasted with the Socialist dominance in the French-speaking parts of the country (except for some low-density rural areas). While this is not in itself a proof of the sectionalist appeal of the Catholic party in Flanders, it strongly suggests a regional-ethnic coloration of Catholic support.[9] Third, there is the evidence, some of which is presented later in this paper and some of which is based on survey data (Delruelle et al., 1970; Hill, 1974), of a high degree of heterogeneity of the social bases of support for the party. Heterogeneity is exactly what one would expect in situations of sectionalism, or the failure of national political integration (Hechter, 1975:218–9), in which political orientations are determined more by status-group membership than by social structural considerations such as class membership. Finally, during the earlier phase of growth of electoral support for the Flemish movement during the interwar period, Flemish success seems to have been concentrated in rural areas which were also the ones in which the Catholic party was most dominant. (For an observer with some knowledge of the social geography of Belgium, the easiest way to see this is to examine the detailed map of the evolution of political alignments at the canton level contained in De Smet et al., 1958.) Again, this historical pattern suggests a high degree of interchangeability of Catholic and Flemish votes as expressions of ethnic feelings.[10]

---

[6] See Nielsen (1978a:chap. 5, Appendix D) for a detailed discussion of the electoral data and criteria of selection of the sample of cantons. Electoral data are from De Smet et al. (1958) and Ministère de l'Intérieur (1965; 1968; 1974).

[7] If the Flemish area of Belgium as a whole, or the individual voter, were units of analysis, weighted averages of support (controlling for the size of the canton) would be the appropriate statistics. Canton averages presented in Figure 1 may also differ from published results on average supports in the Flemish region (e.g., Hill, 1974) because of the stricter selection of units. However, the figures presented by Hill and the ones in Figure 1 are very similar.

[8] I am grateful to an anonymous reviewer for requesting a proper clarification of this important issue.

[9] I do not have the data corresponding to the central and southern areas of the country to be able to carry out a residual analysis of party support similar to the ones performed by Hechter (1975) and Ragin (1977).

However, for the interchangeability and transfer hypotheses to hold, it would have to be the case that, at the canton level, Flemish success is roughly matched by a comparable loss of Catholic support. This is what the symmetry of the curves in Figure 1 suggests. But the curves in Figure 1 are based on electoral data aggregated at the regional level and may conceal a serious ecological fallacy: it is not, on the whole, because the aggregate evolutions of Catholic and Flemish supports are mirror images of each other that the same holds true at the canton level. As a matter of fact, it is not at all the case. In analyses described in detail elsewhere (Nielsen, 1978a and Nielsen, 1978b), I plotted the trends in support for both the Catholic and Flemish party during the 1954 to 1974 period against a measure of the political diversity of a canton in 1950. The trend in party support is computed as the slope of the regression line of support against time for each individual canton and constitutes a summary measure of the success or demotion of a party over the twenty-year period. The trend for the Catholic party was correlated .757 with political diversity, a correlation significant at the .001 level. In order for the transfer hypothesis to hold at the canton level, one would require an equally strong, but negative, correlation between the same exogenous variable, political diversity, and the trend for the Flemish party. The correlation between Flemish trend and diversity is only −.142, with the significance level .083. These results mean that, by and large, *the cantons in which the Catholics lost much support are not the same as the ones in which the Flemish party gained most.*[11] This result largely rules out the simple transfer hypothesis and the contention that Catholic and Flemish voting are alternative expressions of ethnic solidarity after World War II. At the very least, one has to admit that, even if Catholic and Flemish voting both represent expressions of status-group solidarity, they are very different ones indeed. This conclusion, together with the argument for a greater face validity of Flemish support as an indicator of solidarity presented above, justifies the focus on Flemish vote in the rest of this paper.

---

[10] It is quite possible that the history of the Flemish party success between the two wars is consistent with the reactive ethnicity interpretation. It may be that the social-structural correlates of ethnic solidarity are very different if one compares the pre-World War II (1919–1939) and current manifestations of the movement. The quantitative study of the Flemish movement between the wars has rich theoretical possibilities, but is complicated by the fact that the Belgian government was impoverished immediately after World War I and during the Great Depression, so that only the data from the 1920 and 1930 censuses which had immediate legal implications (e.g., for the allocation of seats in legislature) were published. (See the introduction in the first volume of the 1947 census: Institut National de Statistique, 1954.) It appears that more comprehensive data are still available but would have to be coded from the old handwritten records kept by the Institut. The electoral data for the period are readily available at the canton level from De Smet et al. (1958).

[11] Of course, I was as surprised by these results as any observer familiar with the current evolution of political alignments in Belgium is likely to be, since it seems to have been a consensus (sometimes embodied in the complaints by Catholic party leaders) that the Volksunie was draining away a large fraction of electoral support previously allocated to the Catholic party. However, I believe that the argument about the discrepancy between the relationships of Catholic and Flemish trends with the exogenous political diversity variable is rather strong. Its logic is isomorphic with the logic of instrumental variable estimation in statistical methodology. In this case, the transfer hypothesis implies a constraint on the coefficient of the relationship between Catholic and Flemish trends such that the coefficient between the two trends should be approximately equal to −1. Then, any exogenous (instrumental) variable which has a strong causal relationship with one of the trends (a purely mechanical, spurious relationship would do, too) should have an almost perfectly inverse relationship with the other trend. The numbers presented in the text (correlation coefficients) reveal that this is not the case. Note that the same conclusion would have been reached on the basis of different statistics: the slopes of the two plots are not at all the inverse of each other. The conclusion even holds under very qualitative criteria of scientific confirmation. While the plot of Catholic trend is strikingly linear, the plot of Flemish trend against diversity is as strikingly curvilinear. I argue elsewhere (Nielsen, 1978b) that this discrepancy may be due to the effect of the conduciveness of the system of political alignments on mobilization by *any* new party.

In the next section, I propose to analyze variations in electoral support for the Flemish movement and the three traditional parties, both over time and across socially heterogeneous environments, within the framework of a dynamic model of political mobilization. In order to estimate the coefficients of the mobilization model empirically, it is necessary to have indicators of the socioeconomic composition of the cantons. Census data are available for 1961 and 1970. Values of the socioeconomic indicators for each election year at the canton level were obtained by aggregating census figures at the commune level and intra- or extrapolation from the 1961 and 1970 data.[12] I discuss the socioeconomic indicators in more detail in Section 5.

4. A DYNAMIC MODEL OF ETHNIC SOLIDARITY

Given the data available (electoral results for nine elections and extrapolated census figures corresponding to the same time points), one could, in principle, carry out nine cross-sectional analyses of the social bases of Flemish support. However, mobilization takes time. A new party has to advertise its ideology and convince voters to switch their allegiances. The mobilization process is inherently dynamic. Coleman (1968) has shown that cross-sectional analyses of a dynamic process are misleading when the process has not reached equilibrium. An examination of Figure 1 suggests that Flemish support was away from equilibrium during most of the period under investigation. Therefore, my analytical strategy is to model explicitly the dynamics of mobilization for the Flemish movement and for the other three parties.

The simple dynamic model of mobilization assumes that the equilibrium support for a party in a canton depends on the composition of the social environment, as measured by a set of socioeconomic variables to be specified below. Since the exact form of the functional relationship between equilibrium support and the social environment is not known, I assume a linear one, which is the simplest possible:

$$P^* = c_0 + c_1S_1 + c_2S_2 \ldots + c_KS_K \qquad (1)$$

Equation (1) represents the equilibrium support P^* of a party in a canton as a linear function of K socioeconomic characteristics $S_1, \ldots, S_K$ of the canton. The equilibrium support of a party may be thought of as the carrying capacity of the party (a form of collective organization) in a social environment characterized by a particular set of values of the socioeconomic variables S. The carrying capacity corresponds to the maximum level of support achieved by a party in a social environment once the mobilization process is completed.

However, parties do not reach their carrying capacity of support immediately in a social environment, because mobilization is not instantaneous. Consequently, support for a party cannot react instantly to variations in the carrying capacity of support caused by changes in the composition of the social environment. Moreover, parties are likely to differ with respect to the speed with which they can recruit their potential memberships. To capture these dynamic aspects, I represent the growth in support for a party, or rate of mobilization, as a function of the discrepancy between current support and the carrying capacity:

$$dP/dt = -b\,(P^* - P) \qquad (2)$$

In Equation (2), P denotes the current level of support and P^* is the carrying capacity defined in Equation (1). dP/dt, the derivative of P with respect to time, represents the rate of mobilization. Equation (2) describes the way in which support for a party is assumed to grow or decline. The growth in support is proportional to the discrepancy between carrying capacity and current participation. The model assumes that b is negative. Then, −b is positive and support for the party increases (dP/dt is positive) when current support is smaller than the carrying capacity in the social environment. When current support P is larger than P*, support declines. In both cases, P reaches its equilibrium value P* as time elapses. The absolute value of the parameter b determines the speed at which the process of mobilization (or demobilization) takes place. A large absolute value of b means that the support adjusts quickly to its carrying capacity in the social environment; a small absolute value of b indicates that the mobilization process is slow. In the next section, I propose substantive interpretations of the coefficient b in terms of differences in the nature of the mobilization process across parties. Substituting (1) into (2) and rearranging the terms yields the full model:

---

[12] Census data in machine-readable form at the commune level for 1961 and 1970 were obtained through the Belgian Archives for the Social Sciences (B.A.S.S., 1976) and Dr. Mark Van Naelten of the Katholieke Universiteit te Leuven.

$$dP/dt = bP - bc_0 - bc_1S_1 - bc_2S_2 - \dots - bc_KS_K \qquad (3)$$

The differential Equation (3) represents the growth of support as a function of both current support P and the current values of K socioeconomic characteristics S of a canton. The solution of (3) is (Coleman, 1968):

$$P_t = P_0e^{bt} + (1-e^{bt})c_0 + (1-e^{bt})c_1S_1 + \dots + (1-e^{bt})c_KS_K \qquad (4)$$

Equation (4) provides the leverage needed for estimation of the coefficients of the dynamic model (assuming that the time interval between P_0 and P_t is equal to 1) since it is equivalent to:

$$P_t = b'P_{t-1} + c_0' + c_1'S_{1,t-1} + \dots + c_K'S_{K,t-1} + W_t \qquad (5)$$

where $b' = e^b, c_0' = (1-e^b)c_0', \dots, c'_K = (1-e^b)c_K$. In Equation (5), support at time t is a linear function of its value at the preceding election and the lagged values of the socioeconomic variables $S_1, S_2, \dots, S_K$. The coefficients of Equation (5), in which W_t denotes a random disturbance, can be estimated by regression techniques. The coefficients of the dynamic model (3) can be recovered quite simply from estimates of the coefficients of (5): $\hat{b} = \ln\hat{b}'$ and $\hat{c} = \hat{c}'/(1-\hat{b}')$. A similar procedure is used by Nielsen and Hannan (1977) in the context of a discrete time dynamic model (see also Doreian and Hummon, 1976).[13]

Equation (5) has the familiar form of a linear equation with lagged dependent variable. Given the data available, (5) could be estimated using electoral results, and the corresponding values of the socioeconomic variables, for any one of the eight pairs of election years. Rather than estimate (5) separately in eight different ways, I pooled all the data into a single model. This technique of pooling time-series and cross-section data has been discussed extensively by Hannan and Young (1977). It permits us to deal satisfactorily with an estimation problem that plagues almost all analyses of panel data in sociology: autocorrelation of disturbances. Disturbances are correlated when stable characteristics of a canton, such as the distance from the capital, have been omitted from the formula (1) for the carrying capacity of support for a party. These unmeasured features of the social environment are forced into the disturbance term W_t in (5). Since they presumably operate at every point in time, disturbances are correlated over time and with the lagged dependent variable. Consequently, ordinary least-squares estimators applied to (5) are biased and inconsistent. The possibility of bias in estimates of the coefficient b′ of the lagged dependent variable is particularly troublesome since b′ enters into the computation of all the other coefficients of the model (the c coefficients).

---

[13] Coleman (1968) proposes more complicated manipulations of the regression coefficients c′ in (5) in order to obtain estimates of the parameters bc of the differential Equation (3) in canonical form. However, Rosenfeld and Nielsen (1978) argue that the substantive interpretation of the parameters of a differential equation in canonical form is awkward. For my purpose, the coefficients to be interpreted substantively are the dynamic coefficient b and the coefficients c of equilibrium support. These can be recovered from the estimated regression coefficients of Equation (5) with computational formulas which involve only one subtraction and a few divisions and are simpler than the ones proposed by Coleman (1968).

Autocorrelation of disturbances is not the only estimation problem in this case. My preliminary analyses indicated that the absolute values of the residuals increase sharply with the size of the canton, as measured by the total number of valid votes. This finding suggests that the distribution of disturbances is heteroscedastic (the variance of disturbances is not constant). Heteroscedasticity implies that ordinary least-square estimators of (5) are inefficient. To control for both the auto correlation of disturbances and heteroscedasticity, I used a generalized least-squares estimator labelled WGLS ("weighted generalized least-squares"). The derivation of the WGLS procedure is quite technical. A detailed discussion may be found in Nielsen (1978a:chap. 6, Appendices A and B).[14]

In the next section, I present WGLS estimates of the coefficients of the dynamic model of mobilization for each one of the four major parties: the Catholic, Socialist, Liberal and Flemish parties. To control for the homogeneity of the process, I use only data pertaining to the seven election years from 1954 to 1975. This strategy is justified by the fact that the evolution of Flemish support in 1949 and 1950 seems atypical with respect to the dynamic model of mobilization (see Figure 1).

5. RESULTS

To analyze empirically the social bases of support for the Flemish movement, it is necessary to specify more precisely the socioeconomic variables S_K which determine the carrying capacity of support for the party (see Equation [1]). Among those available from BASS and Mark Van Naelten (see footnote 12), I selected a set of six variables chosen in such a way as to constitute as detailed a picture as possible of the phenomenon of modernization. The substantive aspects of these variables will be discussed in more detail with respect to various theories of ethnic solidarity in the presentation of the results below.

S_1 : number of housing units in one-family houses. This is a negative measure of urbanization—a high value of this variable indicates a low level of urbanization. (For a discussion of this indicator in the Belgian context see Jouret, 1972.) More traditional measures of urbanization, such as the proportion of individuals living in cities with populations greater than a given number, may be more familiar to sociologists but could not be used here since a single city may contain several units of analysis (cantons). Note that the variable is, quite literally, a negative measure of the extent to which housing units are stacked up on top of each other. Therefore, S_1 may be high both in wealthy suburbs and in rural environments.[15]

S_2 : male labor force in agriculture and fishing, an indicator of occupational concentration in traditional primary activities.

S_3 : floor area (in 100 m^2) used for industry, an indicator of industrialization.

S_4 : male and female labor force employed in commercial activities, a measure of employment in the tertiary sector.

S_5 : active population working outside the commune of residence. This is a measure of mobilization of the peripheral population in Deutsch's (1953) sense. S_5 captures the volume of movements of the population across the boundaries of the local setting and the density of interactions with individuals outside. While the mobilization indicator has no direct geographical meaning at the canton level (being computed by aggregating figures at the commune level) and measures, therefore, both the density of interactions within the periphery and between the periphery and the center, I included it as a control variable because the reactive ethnicity and competition theories both assume it is an important factor. Hechter (1975:43) argues explicitly that the density of within-community contacts should facilitate ethnic solidarity. Competition theories generally suggest that center-periphery contacts (and the increased likelihood of competition) facilitates mobilization on the basis of ethnicity.

---

[14] The WGLS procedure involves estimating various components of the variance of the error term in (5). The formulas I used are based on the work of Henderson, Sr. (1952; 1963), Henderson, Jr. (1971) and Searle (1971). The model also involves assumptions on the behavior over time of the exogenous variables S. Because the values of the exogenous variables were obtained by extrapolating 1961 and 1970 figures, it was impossible to compute accurate estimates of the change in the S variables between any two election years. Therefore, I chose to assume that the exogenous variables are relatively constant between elections. See Coleman (1968) for a discussion of the behavior of exogenous variables in a dynamic model.

[15] This problem of interpretation leads to the suspicion that there may be mechanisms underlying the measurement of social reality which, like the uncertainty principle in physics, imply that an increase in precision (in this case, a finer-grained measure of urbanization) has to be compensated somehow by a loss elsewhere (here, straightforward interpretability).

S_6 : total income (in millions Belgian francs).

The set of six indicators seems to provide a clear picture of the most important aspects of the process of modernization: increased urbanization is captured by S_1, the progressive shift in the occupational distribution from the primary to the tertiary sectors by variables S_2,S_3 and S_4. The mobilization indicator S_5 monitors the degree of insertion of the local community into the larger, national network of interactions. Finally, S_6 is a straightforward measure of the relative share of economic rewards a local community has been allocated as a result of the entire process. With that selection of independent variables, Equation (5) is suitably specified for empirical estimation. I estimated the coefficients of the model (5) with P_t measured as the number of votes for the Flemish movement at election t. For comparison purposes, and as a partial check of the validity of the mobilization model, I also estimated the coefficients for the Socialist, Liberal and Catholic parties. The weighted generalized least-squares estimates for the four parties are presented in Table 1.

a. The carrying capacity of support for the Flemish movement. It would be possible to assess the effects of the various characteristics of the social environment on Flemish support directly from an

No. of cases: 96.
No. of time periods: 6.
Total No. of cases in the pooled regressions: 576.
Weighting variable: No. of valid votes at time t.
* Significant at the .05 level.

[a] Electoral returns for 1958, 1961, 1965, 1968, 1971 and 1974 are used as dependent variables. Lagged party supports are measured from 1954 to 1971. Values of other independent variables are obtained by intra- and extrapolation of 1961 and 1970 census figures. These are estimates of the coefficients of Equation (5):

$$P_t = b'P_{t-1} + c_0' + c_1 'S_{1, t-1} + c_2 'S_{2, t-1} + c_3 'S_{3, t-1} + c_4 'S_{4, t-1} + c_5 'S_{5, t-1} + c_6 'S_{6, t-1} + W_t$$

examination of the regression coefficients in Table 1. However, it will be substantively illuminating to compare the effects of the socioeconomic variables across parties. In order to compare the coefficients of a dynamic model across equations, it is necessary to compute the coefficients c of the carrying capacities of support (Equation [1]). These can be recovered quite simply from the regression coefficients in Table 1 (see Section 4). The transformation amounts to a control for differences in the dynamics of mobilization across parties. Estimates of the coefficients c are presented in Table 2. However, coefficients corresponding to different variables are not standardized, and have different metrics (e.g., employment in agriculture and industrial floor area). Therefore it is useful, for comparing coefficients associated with different variables, to refer to the standard errors of estimate of the regression coefficients reported in Table 1.

I discuss the coefficients for the carrying capacity of support of the Flemish movement first. The coefficient of S_1 (housing units in one-family houses) is small (.028) and the corresponding regression coefficient is insignificant. Therefore, urbanization has no effect on ethnic solidarity, controlling for the other variables in the equation. (See the discussion of the indicator of mobilization above.) The coefficient of S_2 (employment in agriculture and fishing) is insignificant, too. This result is important for a comparison of the relative merits of the reactive ethnicity and competition theories of ethnic solidarity. Agriculture is the traditional specialty of Flanders within the Belgian cultural division of labor (Roy, 1968; Hill, 1974). According to the reactive ethnicity model, one would expect social environments which are most affected by differential development of the national economy and kept in the least rewarding and most traditional sectors of activity to be the most favorable to ethnic solidarity. This is not the case: employment in agriculture has no significant effect on the carrying capacity of support for the Flemish movement. This result may correspond to a crucial difference between the nature of ethnic solidarity in Flanders before and after World War II. (See footnote 10.)

The coefficient associated with S_3, the indicator of industrialization, is negative (−.089) and significant. Industrialization affects adversely the success of ethnic solidarity. This finding must be interpreted in light of the fact that the working class in Belgium has traditionally been strongly organized through the network of grass-roots organizations, such as trade unions, of both the Socialist party and the liberal wing of the Catholic party. Intense competition from both entrenched groups, with their specialized institutions, makes penetration difficult for a party with less specific appeal. Such a negative effect of industrialization on Flemish support might have been expected, since the formula for the carrying capacity of support in the dynamic model of mobilization incorpo-

Table 2. Estimated Coefficients of the Differential Equations Model of Mobilization[a]

	Dependent Variable

[a] See Table 1 for definition of variables. These are the coefficients c of the carrying capacity of support (Equation (1)) and the dynamic coefficient b of Equations (2), (3) and (4) estimated from the regression coefficients in Table 1. The computational formulas are discussed in Section 4.

* The corresponding regression coefficient in Table 1 is significant at the .05 level.

rates the effects of competition for support by other parties. The presence of specialized and powerful solidary groups defined on class lines makes for continued salience of the class cleavage in industrial environments.

S_4 (commercial activities) is a measure of concentration of the working population in the tertiary sector. The predictions of the reactive ethnicity and competition theories with respect to the effect of this variable on ethnic solidarity differ considerably. The reactive ethnicity model suggests that, during the process of development, the core attempts to monopolize precisely those activities associated with the tertiary sector which are the most rewarding economically (Hechter, 1974; 1975). Ethnic solidarity is assumed to emerge in areas in the periphery which are denied the full benefit of modernization. Therefore, the reactive ethnicity model would predict a negative association between ethnic solidarity and employment in the tertiary sector. The opposite is true. The coefficient of S_4 is positive (.944) and significant (the corresponding regression coefficient is more than three times the standard error). Employment in the tertiary sector has a positive effect on ethnic solidarity. This finding is consistent with competition theories of solidarity (see Section 2). Competition theories assume that ethnic solidarity is high where the cultural division of labor breaks down. Employment in the tertiary sector measures involvement of the peripheral population in activities previously monopolized by members of the center and also measures a high intensity of competition. Therefore, ethnic solidarity should be positively associated with S_4.

The coefficient of S_6 (income) confirms this pattern. The coefficient of income is positive (1.388) and significant. Controlling for the distribution of the active population within the division of labor, we find that social environments which receive a larger share of the economic rewards of the modern system of production are also those in which ethnic solidarity is most successful. This amounts to a further disconfirmation of the reactive ethnicity model. Structural discrimination, as measured by economic disadvantage, inhibits rather than enhances ethnic solidarity. Such a result does not make sense within the exploitation logic of the reactive ethnicity model.

Finally, the indicator of mobilization (S_5) has a positive effect (.117) on ethnic solidarity. Such a finding is consistent with just about any theory of political mobilization on the basis of inclusive ethnic boundaries. The measure of mobilization captures the intensity of both intra- and intercommunity contact. Therefore, the positive effect is consistent with both the reactive ethnicity and competition theories of ethnic solidarity.

Clearly, the reactive ethnicity model of solidarity proposed by Hechter (1974; 1975) is inconsistent with these empirical results. Employment in agriculture and fishing, the traditional specialty of Flanders within the cultural division of labor, is unrelated to ethnic solidarity. Solidarity is enhanced, by contrast, by indicators of modernization such as employment in the tertiary sector and a large share of the rewards associated with the modern production system. The very same findings lend support to the competition theories of solidarity summarized in Section 2. An increased share of resources and a high proportion of the labor force in the most modern sector of activity facilitate mobilization on the basis of ethnic, as opposed to universalistic, boundaries. However, the negative effect of industrialization indicates that ethnicity is less successful in competition with universalistic (occupation related) bases of collective action in working-class environments.

As a partial check of the validity of the dynamic model of mobilization, I also computed the coefficients c of the carrying capacity of support for the Socialist, Liberal and Catholic parties (Table 2). If the results with respect to the social bases of Flemish support are to be trusted, results for the three other parties should be largely consistent with what is known about the traditional bases of support for these parties (see, for example, Hill, 1974).

When comparing the four columns of Table 2, the first, global impression is that coefficients of Catholic support corresponding to the three indicators of the occupational distribution (agriculture, industry and commerce) are larger than the coefficients of Flemish support (2.070, .260 and 2.370 for Catholics; .148, −.089 and .944 for the Flemish movement). This pattern is understandable in view of the fact (Figure 1) that Catholic support seems to stabilize at a higher level than the Flemish movement. Coefficients that can be interpreted as measures of the share of support for a party in a social environment partitioned into various disjoint categories are expected to be larger when average support for the party is larger.

The large effect of employment in agriculture (2.070) on Catholic support is consistent with the traditional predominance of the party in rural areas. The negative effect (−1.536) of this variable on Socialist support also confirms the historical weakness of the Socialists in these areas. The carrying capacities of both the Socialist and Catholic parties are high in industrial environments (.205 and .260, respectively, for industrial floor area).[16] This finding corresponds to the fact that the two parties compete for the participation of the working class in their grassroots organizations. The coefficients associated with employment in commercial activities, an indicator of the tertiary sector, reveal a high carrying capacity of support for both the Socialist and Catholic parties.

The coefficients associated with income are large and negative for both the Socialists and the Catholics while they are positive for the Liberal party and the Flemish movement. For the Liberal party, the coefficient of income is the only significant one in the equation—this fact suggests an elitist and undifferentiated basis of support. The positive effects of income on both Liberal and Flemish support is interesting. This finding suggests that the Liberal party, because of its longstanding position in favor of Belgian unity, and the Flemish movement represent the two conflicting sides of the subnational cleavage. (The two parties have been the most successful in Flanders after World War II. See Figure 1.) As the effect of structural discrimination decreases, or is reversed, the social environment becomes less favorable to the development of class-based mobilization in the periphery and more sensitive to issues related to subnationalism.

Overall, results with respect to the social bases of support of the Socialist, Liberal and Catholic parties largely support the traditional wisdom of Belgian politics. The Catholic party is dominant in rural environments, but also fares well in working-class areas and those with high employment in the tertiary sector. The Socialist party is most successful in the secondary and tertiary sectors. Liberal support is associated with wealth. Such results, insofar as they were expected on the basis of an independent political lore, enhance confidence in the dynamic model of mobilization and the results concerning the social bases of Flemish support.

b. Dynamic aspects of solidarity. The dynamic model of mobilization represented by Equations (3) and (4) (see Section 4) allows explicitly for differences in the speed of mobilization of support for various solidary groups. Speed of mobilization is captured by the magnitude of the absolute value of the coefficient b in Equations (2), (3) and (4). A large $|b|$ indicates that support for the solidary group adjusts quickly to its carrying capacity determined by the composition of the social environment. Substantive interpretations of the magnitude of $|b|$ differ when support for the group is growing or declining on the average. Estimates of the coefficient b for the four major parties in Flanders are presented in the first row of Table 2. All four estimated coefficients are negative, so that mobilization of support should lead to a stable equilibrium.[17]

---

[16] The absolute values of the coefficients associated with the measure of industrialization are typically lower than the coefficients associated with measures of employment in the primary (agriculture) and tertiary (commerce) sectors. This is due to the fact that the metrics of the measure of industrialization (100 square meters) and measures of employment in other sectors (number of individuals) differ.

[17] This finding constitutes a partial check of the validity of the model. A positive value of the coefficient b would imply a meaningless behavior of the political system. When $b > 0$, the model implies that support for the party will increase, or decrease, exponentially depending on the initial value of support above or below the equilibrium value determined by

Both the Socialist and Liberal parties have low absolute values of the coefficient b (.182 and .156, respectively). The small value of |b| for the Socialists, in view of the general decline of support for the party over the period, indicates an enduring strength of party identification. Identification of the Socialist electorate may be strong for several reasons. First, there is the commitment due to the participation in grass-roots organizations of the party such as trade unions, health care plans and credit unions. Second, the Socialist party is associated with anticlericalism in Flanders. Insofar as the psychological cost for the individual of switching from a religious identification has been high, the identification of Socialist voters within a largely Catholic population is stronger. This is a minority type of process (Durkheim, 1966:152–70). Third, evidence presented elsewhere (Nielsen, 1978a: chap. 5) suggests that Socialist support is heterogeneously distributed over the Flemish region and concentrated in working-class neighborhoods. Concentration in specific areas may generate stronger collective pressures against defection. Such contextual effects are often interpreted in terms of the intensity of class consciousness (Boudon, 1967:183–222; Segal and Meyer, 1969; Przeworski, 1974). The second and third arguments above apply also to the Liberal party. However, the network of grass-roots organizations of the party is less comprehensive and powerful than those of the Socialists and Catholics. Inertia in mobilization for Liberals may also result from the faithful support of the French-speaking minority in Flanders, given the unitarianist position of the party (Roy, 1968:162–3).

The two parties that have grown most (the Flemish movement) and declined most (the Catholic party) have the largest absolute values of the coefficient b (.498 and .396, respectively). In general, a large |b| means quick mobilization or demobilization for a solidary group. For a group with growing support, such as the Flemish movement, a large |b| indicates that the group can take advantage of a large pool of prospective members who are only marginally attached to older movements and constitute, therefore, potential defectors. Such a pattern might have been expected for the Flemish movement in view of the historical circumstances in which mobilization on the basis of ethnic lines took place after World War II. Parties based explicitly on the defense of Flemish interests had already succeeded in securing a sizeable support in the Flemish area before the war. Because of the disorganization of the movement after the war, the niche occupied by ethnic solidarity in the political environment was vacated, and was filled by other solidary groups. After the reorganization of the movement, much of the mobilization effort may have been remobilization of a membership poorly identified with second-best competitors. Another factor of swift mobilization may be the lack of investment in a *verzuil* (pillar) of grass-roots organizations competing with those of the major parties for intensive commitment of the population (Hill, 1974). Such a strategy allows for a low cost of participation and facilitates opportunistic recruitment.[18]

The high rate of demobilization for the Catholic party may involve more subtle analytical considerations. The results of Table 2 show that the Catholic party succeeds equally well in environments characterized by high employment in the primary, secondary and tertiary sectors. The Socialist party fares well in industrial and commercial environments but very badly in rural ones. The Flemish movement is especially successful in social environments characterized by a high level of employment in the tertiary sector. The social bases of support for the three parties may be rank-ordered according to their degree of heterogeneity. The Catholic party has a very heterogeneous basis of support, the Flemish movement a very specialized one. The Socialist party is somewhere in

---

exogenous variables. $b < 0$ implies a monotonic convergence of support to the equilibrium value.

[18] I am indebted to Jerome Black of the Department of Political Sciences, McGill University, for suggesting this interpretation of the speed of Flemish success, in a personal communication. His impression is based on records of numerous private conversations with leaders of the Volksunie.

between. (See also Delruelle et al., 1970, for additional evidence based on survey data.) The distinction between heterogeneous and specialized bases of support corresponds to a crucial distinction between generalist and specialist strategies in the population ecology of organizations (Hannan and Freeman, 1977; Nielsen, 1978c).

It may be that the success of a solidary group in keeping its level of participation when a new competitor is introduced in the system varies according to its strategy. Because of the heterogeneity of its basis of support, a generalist is likely to have a fringe membership poorly identified with some of the goals of the group. The new competitor may be able to attract the adherence of this fringe membership quickly. Weaker commitment of the membership of a generalist party would be translated in a dynamic context into a faster decline in competition with a solidary group mobilizing on the basis of an alternative cleavage. The large absolute value of b (.396) for the generalist Catholic party relative to the value of |b| (.182) for the specialized Socialist party is consistent with that hypothesis. However, the evidence presented in Section 3 largely rules out the simple hypothesis that the Flemish movement obtained most of its votes from defections from the Catholic party. The question which then arises is: "Where have all the Catholic votes gone?" to be sung to the well-known tune. Since a large part of these votes has *not* gone to the Volksunie, the only hypothesis left to entertain is a most intriguing one: most of the votes lost by the Catholic party must have been captured by the Socialists and Liberals. In the cantons in which this occurred, it represents a decrease in sectionalism for the Flemish electorate. On the other hand, the vote for the Volksunie must have come from somewhere: if not the Catholic party, then the Socialist and Liberal ones. This suggests that the evolution of political alignments in Flanders after World War II may have been quite complex. In some cantons, Catholic dominance was replaced by a more equal distribution of support between two parties defined on universalistic lines (the Socialists and Liberals), which corresponds to a decrease in sectionalism with modernization. In cantons which were already politically integrated (with low Catholic dominance), voters switched more enthusiastically to the modern form of ethnic solidarity represented by the Volksunie.

6. DISCUSSION AND CONCLUSION

Resurgences of subnational movements and ethnic conflict in modern states are difficult to explain within the classical theoretical frameworks of sociology. In this paper, I contrasted two categories of explanations of such resurgences which involve radically different assumptions. Hechter's (1975) reactive ethnicity model uses a logic of exploitation: ethnic solidarity is viewed as a form of rebellion of a disadvantaged group against the dominant ethnicity. The greater the inequality, the more intense the solidarity within the subordinate group. Solidarity is akin to class consciousness. Wallerstein (1975:24) summarizes the basic argument of the reactive solidarity model as follows: ". . . one can see the recrudescence of ethnonationalisms in industrialized states as an expression of class consciousness of lower caste-class groups in societies where the class terminology has been preempted by nation-wide middle strata organized around the dominant ethnic group."

Competition theories of solidarity suggest, to the contrary, that solidarity emerges as a result of competition between groups for the same occupations, statuses and economic rewards. Resurgences of ethnic solidarity should occur precisely where the pattern of structural discrimination breaks down and status inequalities between groups are diminished. My analysis of the rise of the Flemish movement in Belgium after World War II disconfirms the reactive ethnicity model and lends support to competition theories of ethnic solidarity. Solidarity is more intense in areas which are less discriminated against occupationally and economically.

RECONCILING RACE AND CLASS DIFFERENCES IN SELF-REPORTED AND OFFICIAL ESTIMATES OF DELINQUENCY*

DELBERT S. ELLIOTT AND SUZANNE S. AGETON
Behavioral Research Institute, Boulder

American Sociological Review 1980, Vol. 45 (February):95–110

This paper addresses the general question of whether or not the satisfactory resolution of the methodological criticisms of self-report research will result in greater consistency between self-reported and official data with respect to the race and class distributions of delinquent behavior. We review the specific methodological criticisms of self-report delinquency (SRD) research; discuss the use of a new SRD measure in a national youth study; compare the race/class findings of this study with previous SRD research and with official arrest data; and examine the epidemiological and theoretical implications of these findings. Both class and race differentials are found in this study. It appears likely that the differences between these findings and those in earlier SRD studies are a result of differences in the specific SRD measures used. Additionally, these findings suggest a logical connection between SRD and official measures, and they provide some insight into the mechanism whereby official data produce more extreme race and class (as well as age and sex) differences than do self-report measures. The results of this study also have implications for previous tests of theoretical propositions which used self-report delinquency data. In short, prior self-report measures may not have been sensitive enough to capture the theoretically important differences in delinquency involvement.

Problems of conceptualization, definition, and measurement continue to plague researchers interested in the epidemiology and etiology of delinquency. While most would acknowledge the conceptual distinction between delinquent behavior and official responses to delinquent behavior, these distinctions are not clearly maintained in the measurement of delinquency or in the interpretation and analysis of specific delinquency data. This problem is clearly illustrated in the current controversy over the validity of self-reported (as compared with official) estimates of the incidence and distribution of delinquency in the general adolescent population. Put simply, there are those who argue that police and arrest records provide more accurate and reliable estimates of the social correlates of delinquent behavior than do self-report surveys; others hold the opposite view.

Self-report measures of delinquency provide a different picture of the incidence and distribution of delinquent behavior than do official arrest records. Both types of data indicate significant age and sex differentials, but the magnitude of these differences is much smaller with self-reported data than with official arrest data (Williams and Gold, 1972; Gold and Reimer, 1974; Elliott and Voss, 1974; Illinois Institute for Juvenile Research, 1973; Bachman et al., 1970; 1971; 1978).

At the center of the controversy, however, is the fact that self-report studies generally find no differences in delinquent behavior by class or race (Gold and Reimer, 1974; Elliott and Voss, 1974; Williams and Gold, 1972; Hirschi, 1969; Bachman et al., 1970; 1971; 1978; Illinois Institute for Juvenile Research, 1973), while studies relying upon police and court data report significant differences by both class and race (Wolfgang et al., 1972; Elliott and Voss, 1974; Williams and Gold, 1972; Gordon, 1976; West, 1973; Short and Nye, 1957–1958).

To date, attempts to reconcile this apparent discrepancy between official and self-reported findings have taken one of two approaches. Most recently, researchers have challenged the strength of the empirical evidence for the class differ-

ential in official data. Tittle and Villemez (1977) and Tittle et al. (1978) reviewed earlier published research findings and concluded that the class differences in official data are not clearly established and that the widespread belief in an inverse relationship between class and crime is not based upon sound empirical research findings. Hindelang et al. (1978) have also concluded that police records of juvenile offenses are not strongly or even moderately related to socioeconomic status.[1] On the other hand, the race differential in official data has not been seriously challenged, to our knowledge.

The second and most frequent approach has been to challenge the methodological adequacy of the self-report technique and the adequacy of self-report research. Specifically, critics of self-report research contend:

(1) There are problems inherent in the method itself which make it inaccurate and unreliable. These problems include deliberate falsification, inaccurate recall, and forward and backward telescoping.

(2) There are problems with the construction of measures used in self-report research and with the procedures for administering the measures. These problems concern the lack of representativity in items, item overlapping, imprecise response sets, and the lack of anonymity of respondents.

(3) There are problems with generalizing from self-report studies, due to the almost exclusive reliance upon small, unrepresentative samples.

This paper is concerned with this second approach to reconciling official and self-reported findings with respect to class and race. We will not deal with those problems inherent in the self-report method itself, except to note that available research seems to support both the validity and reliability of the method (Nye and Short, 1956; Erickson and Empey, 1963; Hirschi, 1969; Gold, 1966; Dentler and Monroe, 1961; Hardt and Bodine, 1965; Hardt and Hardt, 1977; Farrington, 1973; Elliott and Voss, 1974; Clark and Tifft, 1966). Instead, we will deal with the correctable problems, i.e., the construction of measures and their administration, as well as representativity and sample size. The general question we will address here is whether or not the satisfactory resolution of these methodological issues in the construction and administration of self-report measures will result in greater consistency between self-reported and official data. More specifically, will the satisfactory resolution of these problems produce race and class differentials in self-reported estimates of delinquent behavior?

The discussion that follows will focus on: (1) the methodological criticisms of previous self-report delinquency (SRD) research; (2) the use of a new SRD measure in a national youth study; (3) a comparison of the race/class findings of this study with previous SRD research and with official arrest data; and (4) the epidemiological and theoretical implications of these findings.

PROBLEMS WITH SRD RESEARCH

Instrument Construction

Much of the controversy over self-report measures involves problems with instrument construction. Primarily, criticism centers on three issues: (1) the question of the representativeness of items employed in SRD measures; (2) problems of item overlap; and (3) limited or ambiguous response sets.

The major criticism concerns the unrepresentativity of the items selected (Hindelang et al., 1975; Nettler, 1974; Farrington, 1973). Trivial and nonserious offenses (e.g., cutting classes and disobeying parents) are often overrepresented, while serious violations of the criminal code (e.g., burglary, robbery, and sexual assault) are frequently omitted. In addition, many SRD measures tend to overrepresent certain behavioral dimensions (e.g., theft) to the exclusion of other relevant delinquent acts. As a result of such selection processes, most existing SRD measures have a restricted focus and do not represent the full range of delinquent acts; this limits the appropriateness of these scales as general measures of delinquent behavior.

---

[1] Hindelang et al. (1978) have also recently studied the extent to which sex and race are differentially related to self-reported and official records of delinquency, and some of their conclusions with regard to the race discrepancy will be cited later.

Another problem is the overlapping nature of items often included in SRD measures, which results in inaccurate estimates of frequency due to duplicate counts of certain events. For example, many SRD measures include a "shoplifting" item, a "theft under $5" item, and a "theft $5–50" item. A single theft event could logically be reported on two of these items. The presence of both a "cutting school" and a "cutting class" item represents another form of measurement redundancy since cutting school necessarily involves cutting classes. This problem is not easily overcome, since a given behavioral event in fact may involve more than a single offense. Nevertheless, item overlapping creates a potential source of error in estimating the volume of delinquent behavior from SRD measures.

The type of response sets typically employed with SRD measures has been another source of criticism. One major concern has been the frequent use of normative response categories such as "often," "sometimes," and "occasionally." This type of response set is open to wide variations in interpretation by respondents, and precludes any precise count of the actual number of acts committed.

Other response sets used to estimate the number of behaviors (e.g., "never," "once or twice," and "three times or more") have been challenged on the grounds that they are not precise categories for numerical estimation, and that numerical estimates based upon such categories may severely truncate the true distribution of responses. With the above set, for example, any number of behaviors in excess of two is collapsed into a single "high" category. While this procedure may allow for some discrimination between youth at the low end of the frequency distribution, it clearly precludes any discrimination at the high end. Thus, a youth involved in three shoplifting offenses during the specified period receives the same "score" as a youth involved in 50 or 100 shoplifting events during the period. This limited set of categorical responses appears particularly problematic when the reporting period involves a year or more and when such items as using marijuana; drinking beer, wine or liquor; and carrying a concealed weapon are included in the SRD measure.

Administration Procedures

The manner in which the measures are administered is also a problematic area for self-report delinquency research. Here the issue concerns: (1) anonymous vs. identified respondents, and (2) questionnaire vs. interview formats.

Many researchers have argued that anonymity has to be guaranteed or youth will not admit certain offenses—probably the more serious, stigmatizing ones. Research on this question suggests that there is slightly more reporting of offenses under conditions of anonymity, but that anonymous/identified differences are slight and statistically insignificant (Corey, 1937; Christie, 1965; Kulik et al., 1968). These findings have led Dentler (as cited in Hardt and Bodine, 1965) to comment that the necessity for anonymity is overemphasized, and that it may in fact lead to reduced involvement by respondents and careless or facetious answers.

On the matter of interview vs. questionnaire formats, the discussion again involves the issue of anonymity, and the belief that self-administered questionnaires are more likely to produce accurate responses than personal interviews. One recent self-report delinquency research study compared results from structured interviews and self-administered check lists, where anonymity was guaranteed under both conditions (Krohn et al., 1974). While seven of the eight offenses were admitted more often under check-list conditions than under interview conditions, none of the differences was significant at the .05 level. Even when education, sex, class, and IQ were controlled, no significant differences were obtained.

Some researchers, most notably Gold (1966), have argued that the interview format has significant advantages for delinquency research in that it permits clarification of specific behaviors and, consequently, the ability to more correctly classify illegal acts. In general, however, there is still controversy over the effects of specific administration procedures when the research is directed toward illegal or socially disapproved behaviors.

Sampling Design and Generality

Another problematic area for self-report delinquency research is that of the generality of findings. Here the question focuses primarily on the adequacy of the sampling designs for: (1) inferences to the adolescent population, and (2) comparisons with official data.

In most cases, SRD measures have been administered to small, select samples of youth, such as high school students in a particular local community or adolescents processed by a local juvenile court. The samples are rarely probability samples, and generalizations (about the adolescent populations sampled) cannot be made with any known degree of accuracy. Only two published studies involve national probability samples.[2]

A further concern is that few cohort studies using normal populations have incorporated a self-report measure in their instruments. This means that the age and sex gradients of SRD measures are not known, a critical fact if this measurement approach is to become more refined and useful. Furthermore, since the studies using self-report measures have almost always been cross-sectional ones, little is known about the dynamics of self-reported behavior over time.

Finally, Empey (1978) notes that national self-report studies have not been conducted on an annual basis and, as a result, it is not possible to discern trends across time or to make direct comparisons with other standard delinquency data such as the Uniform Crime Reports (UCR) or the National Crime Panel (NCP).

THE NATIONAL YOUTH SURVEY

We will now report on a national youth study in which we have attempted to deal with the previously noted methodological criticisms of self-report delinquency research. Our aim will be to see if these improvements in the quality of self-report research have any impact on self-report findings relative to findings from official data.

The National Youth Survey involves a five-year panel design with a national probability sample of 1,726 adolescents aged 11–17 in 1976.[3] The total youth sample was selected and initially interviewed between January and March, 1977, concerning their involvement in delinquent behavior during the calendar year 1976. The second survey was completed between January and March, 1978, to obtain delinquency estimates for the calendar year 1977. The third, fourth, and fifth surveys will also be conducted between each January and March of the years 1979, 1980, and 1981.

The data reported herein are taken from the first survey, completed in 1977. The estimates presented are thus for delinquent behavior during the calendar year 1976.

Construction of New SRD Measure

In constructing the SRD measure for this study, we attempted to obtain a representative set of offenses. Given our interest in comparing SRD and UCR estimates, we began by listing offenses included in the UCR. Any specific act (with the exception of traffic violations) involving more than 1% of the reported juvenile arrests for 1972–1974 is included in the SRD measure.

In addition to the list of specific offenses, the UCR contains a general category, "all other offenses," which often accounts for a high proportion of the total juvenile arrests. To cover the types of acts likely to fall within this general category, and to increase the comprehensiveness of the measure, two general selection criteria were used to choose additional items. First, items which were theoretically relevant to a delinquent lifestyle or subculture as discussed in the literature were selected for inclusion in this measure (Cohen, 1955; Cloward and Ohlin, 1960; Miller, 1958; 1966; Yablonsky, 1962; Short and Strodtbeck, 1965). Thus, additional items—such as gang fighting, sexual intercourse, and carrying a hidden weapon—are included. Second, a systematic review of existing SRD measures was undertaken to locate items that tapped specific dimensions of delinquent behavior not previously included.

---

[2] These are Gold's 1967 and 1972 National Surveys of Youth and the Youth in Transition Study (Bachman et al., 1970; 1971; 1978). Both studies are limited by a restricted set of SRD items and truncated response sets. The Youth in Transition Study also has problems associated with overlapping reporting periods for its reported SRD measures.

[3] The National Youth Survey is funded by the Center for Studies of Crime and Delinquency, NIMH (MH27552), and the National Institute for Juvenile Justice and Delinquency Prevention, LEAA (78–JN–AX–0003). Current funding covers the first three of the five projected annual surveys. The first survey was funded solely by NIMH, the second and third by NIMH and LEAA jointly.

We believe the resulting set of 47 items to be both more comprehensive and more representative of the conceptual universe of delinquent acts then found in prior SRD measures used in major, large-scale studies. The item set includes all but one of the UCR Part I offenses (homicide is excluded); 60% of Part II offenses; and a wide range of "other" offenses—such as delinquent lifestyle items, misdemeanors, and some status offenses. The vast majority of items involve a violation of criminal statutes. (See Appendix A.)

Two separate response sets are being used. Respondents initially are asked to indicate how many times during the past year they committed each act. If an individual's response to this open-ended question involves a frequency of 10 or more, interviewers then ask the youth to select one of the following categorical responses: (1) once a month, (2) once every 2–3 weeks, (3) once a week, (4) 2–3 times a week, (5) once a day, or (6) 2–3 times a day.[4] A comparison of the two response sets indicates high agreement between frequency estimates given in direct response to the open-ended question and frequency estimates based upon the implied frequency associated with the midpoint of the category selected.[5]

A specific attempt was also made to eliminate as much overlap in items as possible. None of the items contains a necessary overlap as in "cutting school" and "cutting class." Although some possible overlap remains, we do not feel it constitutes a serious problem with this SRD measure.

The SRD measure asks respondents to indicate how many times, "from Christmas a year ago to the Christmas just past," they committed each offense. The recall period is thus a year, anchored by a specific reference point relevant to most youth. The use of a one-year period which coincides almost precisely with the calendar year allows for direct comparison with UCR data, NCP victimization data, and some prior SRD data. It also avoids the need to adjust for seasonal variations, which would be necessary if a shorter time period were involved.

Administration Procedures

For the present study, the research design (a longitudinal panel design) precludes a guarantee of anonymity. Therefore, our major concern is to guarantee respondents that their answers will be confidential. This assurance is given verbally as well as being contained in the written consent form signed by all youth and their parents. In addition, a Certificate of Confidentiality from the Department of Health, Education, and Welfare guarantees all respondents that the data and the interviewers will be protected from legal subpoena.

The interview format was selected over the self-administered questionnaire format for several reasons. First, we share Gold's belief that the interview situation (if properly structured to protect confidentiality) can insure more accurate, reliable data. Second, the necessity of securing informed consents from all subjects and the complexity of the present research require, in our judgment, a personal contact with the respondents. Once this contact is made, it seems logical to use the interviewer to facilitate the data collection process and to improve the quality of the data obtained. Finally, some of our previous research suggests that the differences in responding to SRD items in a questionnaire as opposed to an interview format are not significant (Elliott et al., 1976).

---

[4] The categorical response set has led to the identification of some highly episodic events, e.g., 20 shoplifting offenses, all occurring within a two-month period during the summer (an initial response of 20; a categorical response 2–3 times a week, and an interviewer probe revealing that the offenses all occurred during the summer).

[5] The only exception involves the last two (high frequency) categories. At this end of the frequency continuum, estimates based upon the midpoint of the category are substantially higher than the frequency response given directly. The open-ended frequency measure thus appears to provide a more conservative estimate of number of delinquent acts, and the estimates reported here are based upon this response.

The Sample

The 1977 National Youth Survey employed a probability sample of households in the continental United States based upon a multistage, cluster sampling design. The sample contained 2,375 eligible youth aged 11–17 in 1976. Of these, 1,726 (73%) agreed to participate in the study and completed interviews in the 1977 survey.[6] A comparison of the age, sex, and race of eligible youth not interviewed with participating youth indicates that the loss rate from any particular age, sex, or racial group appears to be proportional to that group's representation in the population. Further, with respect to these characteristics, participating youth appear to be representative of the total 11 through 17-year-old youth population in the United States as established by the U.S. Census Bureau (Huizinga, 1978).

Summary of New Measure

In sum, the current SRD measure addresses many of the central criticisms of prior SRD measures.[7] It is more representative of the full range of delinquent acts than were prior SRD measures and involves fewer overlapping items; it also employs a response set which provides better discrimination at the high end of the frequency continuum and is more suited to estimating the actual number of behaviors committed. The choice of a one-year time frame with a panel design involving a one-year time lag is based upon both conceptual and practical concerns. Compared with the other SRD measures, the measure involves a moderate recall period, captures seasonal variations, and permits a direct comparison with other self-report and official measures which are reported annually. And, finally, the study involves a national probability sample of youth aged 11–17.

ANALYSIS OF DATA

Subscales

An earlier paper (Ageton and Elliott, 1978) presented design effects and estimates of the frequency of each specific item on the SRD measure with .95 confidence intervals for the total sample and by age, sex, race, and class. The analysis in this paper focuses upon the total SRD measure and a set of specific subscales. The frequency estimates are based upon the open-ended response set, which provides slightly more conservative frequency estimates than does the categorical response set.

---

[6] At each stage, the probabilities of selection were established to provide a self-weighting sample. Seventy-six primary sampling units were selected, with probability of selection being proportional to size. This sampling procedure resulted in the listing of 67,266 households, of which approximately 8,000 were selected for inclusion in the sample. All 11- through 17-year-old youth living in the selected households were eligible respondents for the study. The selected households generated a total of 2,375 eligible youth. Of these, 649 (27%) did not participate in the study due to (1) parental refusal, (2) youth refusal, or (3) the youth being considered inappropriate for inclusion in the study (e.g., severely mentally retarded). In general, based upon a comparison with 1976 U.S. Census Bureau estimates, the resulting sample of participating youth does appear representative of American youth with respect to age, sex, and race (U.S. Bureau of the Census, 1977). For a detailed description of the sample, see Huizinga, 1978, and Ageton and Elliott, 1978.

[7] While we are concerned with the issues of validity and reliability of the self-report method, we will not deal with these issues here beyond reporting that: (1) we are obtaining data on official police contacts for each respondent and intend to compare self-reports of delinquent behavior with official records of police contact and arrest; and (2) the reliability (internal consistency) of the new SRD measure is quite high (Alpha = .91) for the 1977 survey. We are planning further validity tests with these data, but have nothing to report, yet.

The subscales are based upon Glaser's (1967) offense typology. This particular classification scheme was selected because it offers a logical categorization of offense types while permitting a clear distinction between serious and nonserious crimes.

Glaser's typology encompasses four major types of crime: (1) predatory crimes, (2) illegal service crimes, (3) public disorder crimes, and (4) crimes of negligence. With the exception of category four, all Glaser's types were used.[8]

Furthermore, Glaser acknowledges an additional category called status crimes to encompass those behaviors which at special times and/or for particular classes of people have been illegal. The status crimes category in this national youth study includes all behaviors in the SRD measure which are illegal only when the individual involved is a minor.

In addition, a separate category entitled hard drug use was created to distinguish this type of drug involvement from that of alcohol and/or marijuana use, which are subsumed within the status crimes category and public disorder crimes category, respectively.

Finally, within the predatory crimes category, a distinction was made between crimes against persons and crimes against property. This differentiation separates violent crimes against people from other serious offenses which do not involve confrontation with another person.

Thus, the final offense typology is composed of the following six subscales:

(1) predatory crimes against persons (sexual assault, aggravated assault, simple assault, and robbery);
(2) predatory crimes against property (vandalism, burglary, auto theft, larceny, stolen goods, fraud, and joyriding);
(3) illegal service crimes (prostitution, selling drugs, and buying/providing liquor for minors);
(4) public disorder crimes (carrying a concealed weapon, hitchhiking, disorderly conduct, drunkenness, panhandling, making obscene phone calls, and marijuana use);
(5) status crimes (runaway, sexual intercourse, alcohol use, and truancy);
(6) hard drug use (amphetamines, barbiturates, hallucinogens, heroin, and cocaine).

Table 1 presents the mean frequency of self-reported delinquency by race[9] and class[10] for the total SRD measure and for each of the subscales. The statistical tests involve a one-way analysis of variance on these means.[11]

---

[8] Category Four, crimes of negligence, was excluded because it contains predominantly automobile infractions which were not included in the SRD measure.

[9] Because of the small number of Mexican-American respondents (N = 72) and some obvious clustering effects for this ethnic group, the accuracy of the estimates of variances is questionable, and we have not included this group in the analysis. The same situation holds for the residual "other" category (N = 32). Comparisons are, thus, limited to whites (Anglos) and blacks.

[10] The social class measure employed in this analysis is the Hollingshead two-factor index (Hollingshead and Redlich, 1958) as applied to the principal wage earner in each youth's family. Hollingshead Classes I and II—involving primarily professional managerial occupations and college level educations—are collapsed to make the "middle" class category. Class III—primarily owners of small businesses, clerical workers, and persons in sales occupations and skilled manual occupations, with high school or some college work completed—constitutes the "working" class category.

Classes IV and V—primarily semiskilled persons and those in unskilled manual occupations with high school or lower levels of education—make up the "lower" class category.

[11] It should also be noted that the statistical tests are based upon a simple random sample design. The effect of our departure from this design is probably in the direction of inflating the F values. However, the design effects are small, suggesting that the effect of this departure is not a serious one. For example, the average design effects on items in the total SRD measure are as follows: Males = 1.13; Females = 1.12; 11–12-year-olds = 1.14; 13–15-year-olds = 1.08; 16–17-year-olds = 1.05; Middle Class = 1.05; Working Class = 1.22; Lower Class = 1.09; Whites = 1.14 and Blacks = 1.15. Further, unless otherwise specified, statistical significance refers to probabilities $\leq .05$. Because of our sample sizes, the statistical tests employed are rather powerful. An examination of Table 1 indicates very large variances and, even when significant differences in means are found, it is clear that the distributions being compared overlap substantially.

Race and Class Differentials

Unlike most previous self-report studies, we find significant race differences for total SRD and for predatory crimes against property. Blacks report significantly higher frequencies than do whites on each of these measures. In both cases, the differences in means are substantial. With respect to total offenses, blacks report three offenses for every two reported by whites. For crimes against property, blacks report more than two offenses for every offense reported by whites.

While there is a substantial difference in mean scores on the crimes against persons scale, it is not statistically significant. The difference in the total SRD score appears to be primarily the result of the very high level of property crimes reported by blacks.

We also observe a class differential for total SRD and for predatory crimes against persons. For total SRD scores, the difference is between lower socioeconomic status youth and others; i.e., there does not appear to be any difference between working- and middle-class group means.

The differences are greater, and the trend is more linear, for the crimes against persons scale means than for total SRD. Lower-class youth report nearly four times as many offenses as do middle-class youth and one-and-one-half times as many as working-class youth. There is also a substantial class difference in the mean number of crimes against persons, but this difference is not statistically significant. There are clearly no substantial differences in means for any of the remaining subscales.

A two-way analysis of variance (race × class) was also completed with the total SRD measure and each of the subscales. In every case, the direct effects observed in the one-way analysis of variance were replicated and no significant interaction effects were observed.

COMPARISONS WITH PRIOR STUDIES

Our basic concern in this analysis will now be to ascertain: (1) the comparability

Table 1. Mean Frequency of Self-Reported Delinquency by Race and Class

of the general findings reported here with other SRD findings, and (2) the extent to which these findings might offer some insight into the discrepancy between self-report and official measures of delinquency.

While we have not reported findings from this study relative to the age and sex distribution of delinquent behavior, they are generally consistent with those from other large-scale self-report studies (Hirschi, 1969; Williams and Gold, 1972; Illinois Institute for Juvenile Research, 1973; Gold and Reimer, 1974; Elliott and Voss, 1974). However, the findings relative to the distribution by race and class are not consistent with these earlier studies, none of which report significant differences in the mean frequencies of self-reported offenses by race or class.[12]

In this study, the black/white differential in total offenses is nearly 2:1; and for predatory crimes, over 2:1. Class differences in total offenses are significant and, while the differences are not large, they are in the traditionally expected direction, with lower-class youth reporting higher frequencies. The trend in the previously referenced self-report studies is generally in the opposite direction.

In this study, class differences are clearer on the predatory crimes against persons scale than for total SRD scores; the trend is more linear, in the expected direction, and of greater magnitude (lower:middle = 3:1).

In an effort to determine if this basic difference in findings is due to the differences in the SRD measures employed, we undertook several additional analyses. We "re-scored" the frequency estimates in two ways to approximate the frequency ranges used in the earlier studies. Since our focus is upon those scales where significant class and race differences are observed, our discussion will be limited to the total self-report measure and the two predatory subscales.

First, a comparison of the proportions of youth reporting one or more offenses on each of these scales reveals no statistically significant class or racial differences. Second, all frequencies of three and above on each item in the SRD measure were re-scored as a 3 to approximate the frequency ranges used in the Richmond Youth Study (Hirschi, 1969), the Delinquency and Dropout Study (Elliott and Voss, 1974), and the 1967 and 1972 National Surveys of Youth (Williams and Gold, 1972; and Gold and Reimer, 1974). Frequency scores on items were then summed across items to generate new scale frequencies and means. With one exception, an analysis of race and class differences on these frequency scores reveals no significant differences. The one exception involves a small (but significant) class difference on the predatory crimes against persons scale.[13] The class differential in this case is in the same direction but substantially smaller than that observed with the original scoring.

These two analyses indicate that the extended frequency range used in this study does, in fact, contribute to the difference in findings relative to race and class. Had we used the proportion of youth committing one or more offenses, or a 0–3 range similar to that used in the 1967 and 1972 National Surveys of Youth, our conclusions relative to class and race differences would have been similar to those reported for the earlier self-report studies.

High-Frequency Offenders

Since the above analyses indicate that differences were not occurring at the low end of the frequency distribution (with one exception), we examined race and class differences at several points along the original frequency distribution, with a particular interest in the high end of the

---

[12] Williams and Gold (1972) report a white/black race differential for seriousness of self-reported delinquency behavior, but no difference in frequency. They also report a significantly higher seriousness for higher socioeconomic status (SES) boys, but no differences in frequency by SES. We have not considered seriousness here but, to the extent that our predatory crime subscales reflect the more serious offenses, our data would support the race differential and contradict the direction of the class differential in seriousness as reported by Williams and Gold.

[13] Mean frequencies were as follows: Lower = 2.02; Working = 1.74; Middle = 1.38.

Table 2. Percentage of Respondents Reporting Specific Levels of Delinquency by Race and Class

	Total Self-Reported Delinquency				
	Race		Class		
Number of Offenses Reported	White %	Black %	Lower %	Working %	Middle %
0–24	71.8	67.6	71.7	72.3	70.9
25–49	11.0	8.1	10.6	9.4	11.5
50–199	13.1	15.4	11.4	14.4	14.4
200+	4.1	9.8	6.3	3.9	3.2
	Predatory Crimes Against Property		Predatory Crimes Against Persons		
	Race		Class		
Number of Offenses Reported	White %	Black %	Lower %	Working %	Middle %
0–4	70.6	70.7	77.3	80.0	84.6
5–29	24.1	22.7	18.2	16.1	13.8
30–54	3.4	2.4	1.7	2.1	.8
55+	1.9	4.2	2.8	1.8	.8

frequency continuum. The results of this analysis are presented in Table 2.

The data in Table 2 indicate that the original differences, by both race and class, are due in large part to the relative differences at the high end of the frequency continuum. For example, at the low end of the frequency distribution, the white/black ratios are close to 1:1; but at the high end of the continuum the ratios are greater than 1:2.[14] For class, the lower-class to middle-class ratios at the low end are again close to 1:1; but at the high end the ratio is 2:1 for total SRD and over 3:1 for predatory crimes against persons.

Not only are the relative *proportions* of blacks and lower-class youth higher at the high end of the frequency continuum but also, within the high category, blacks and lower-class youth report substantially higher *frequencies* than do whites and middle-class youth.

Lower-class youth in the high category on the total SRD measures (scores ⩾ 200) report over one-and-one-half times as many offenses as do middle-class youth in this category. On the predatory crimes against persons scale, lower-class youth in the high category (scores ⩾ 55) report nearly three times as many offenses as do middle-class youth in this category. Among those in the high category on the predatory property scale, blacks report over one-and-one-half times as many offenses as do whites.

The one exception to the above generalization is that blacks and whites within the high category on the total SRD measure have approximately the same mean frequencies. The black/white differential on this measure thus appears to be more simply the result of differences in proportions of blacks and whites in the high category.

In any case, blacks and lower-class youth are found disproportionately among high frequency offenders. Prior self-report measures were unable to detect this differential involvement because they used response sets which are sensitive to differences only at the low end of the frequency continuum. We thus conclude that the use of open-ended frequency responses does, in fact, contribute to our finding both class and race differentials.

Range of Offenses in SRD Measure

We also believe that the broader range of offenses included in our SRD measure has some effect on these findings. An item-by-item analysis indicates that the particular set of items included in a measure can have a major impact on observed ethnic and class differentials. For example, the predatory crimes against persons scale includes four types of offenses: sexual assault, aggravated assault, simple assault, and robbery. Mean frequencies, by race, on the three types of assault offenses are as follows:

Offense Type	Whites	Blacks	Ratio
Sexual Assault	.03	.15	1:5
Aggravated Assault	.12	.50	1:4
Simple Assault	2.07	1.05	2:1
Total Assault	2.22	1.70	1:1

With respect to all three types of assault, these data indicate a major difference in frequency, by race. They suggest that measures which include only simple assault items do not have a proper representation of assault items. Given the tendency of prior self-report studies to exclude the more serious assault items, findings from such studies are likely to minimize the racial differences regarding assaultive behavior.

---

[14] For purposes of discussion, the low end of the frequency distribution refers to total SRD scores ⩽ 24 and predatory crime against persons and property scores ⩽ 4. The high end refers to total SRD scores ⩾ 200 and predatory crimes against persons and property scores ⩾ 55.

Even when all three types of assault are represented, an analysis involving a summary assault measure would obscure, in this case, important differences by type of assault. For example, the magnitude of sexual and aggravated assault offenses is so small, compared with that of simple assault offenses, that the inclusion of the latter in a summary measure conceals major differences in the other items and even reverses the direction of the differential.

While assault items have been used for illustrative purposes, we believe the problem to be a general one. The inclusion of both very high and very low frequency items in a single measure may obscure important differences, often differences in seriousness. This is because nonserious offenses tend to be reported frequently, while serious offenses are reported infrequently.

Weighting SRD Items

For some purposes, it may be instructive to weight each item so that its potential contribution to the total score is the same as that of any other item. In this case, no single high frequency item can dominate the overall score. One procedure for accomplishing this weighting is to transform item frequency scores into standard scores and then add them into a total scale score. This transformation was performed, and the results are presented in Table 3.

With respect to class differences, this transformation confirms the earlier findings observed with raw frequencies. Significant class differences are observed for total SRD scores and predatory crimes against persons scores, but not for predatory crimes against property scores. In both cases, the significance levels are higher when item scores are transformed into standard scores prior to summing.

Table 3. Mean Standardized Scores for Selected Scales by Race and Class

	Total Self-Reported Delinquency	Predatory Crimes Against Persons	Predatory Crimes Against Property
RACE			
White	−.2452	−.0860	−.0072
Black	1.5317	.4038	−.0117
F	3.870	8.179	.001
Probability	≤.05	≤.005	NS
CLASS			
Lower	.7375	.2194	−.0905
Working	.1131	−.0746	.1501
Middle	−1.3341	−.2486	−.080
F	3.771	5.159	1.975
Probability	≤.02	≤.006	NS

With regard to racial differences, the black/white difference on the total SRD measure remains, but it is weaker than that observed with raw frequency scores. More importantly, with this transformation the race difference on the predatory property crimes scale (observed earlier) is not replicated. There is essentially no black/white difference in property crimes when separate property offenses are adjusted so as to have the same magnitudes. This change suggests that the higher raw frequency predatory property scale mean for blacks is largely the result of higher frequencies on selected offense items. A review of item specific means confirms that this is indeed the case.

The mean number of vandalism offenses reported by blacks is over three times that of whites, and their mean number of evading payment offenses is over five times that of whites. These two nonserious offenses are relatively high frequency offenses for all youth. The individual item means for blacks are equal to or lower than those of whites on all serious offenses (felonies) included in this scale. Further, with one exception (family theft), means for blacks on all theft items are equal to or lower than those of whites. Thus, the initial racial differences on predatory property offenses are the result of large differences in vandalism (property destruction) and evading payment offenses, and not differences in theft offenses or serious property offenses.

Whereas there are no statistically significant racial differences in predatory crimes against persons offenses when unadjusted frequencies are used, the use of standard scores results in significant differences, with blacks reporting significantly higher scores. The direction of the racial differential is the same as that observed with the use of unadjusted frequencies, but the differential is stronger and statistically significant when standard scores are used.

As noted earlier in the discussion of specific assault items, simple assault is a relatively high frequency offense compared with the other offenses against persons, and whites report substantially higher frequencies than blacks on this offense. On the more serious offenses against persons, magnitudes are relatively low, but blacks report substantially greater frequencies than do whites on most of these items. The only exception involves robbery; here, the black and white means are identical. The transformation of item scores thus results in a greater racial differential than that observed with unadjusted frequencies.

The review and analysis of prior SRD studies by Hindelang et al. (1978) led them to conclude that racial differentials increase with the severity of the offense. The data in our National Youth Survey provide only partial support for that generalization. With respect to offenses against persons, the black/white differential is indeed greater for serious (as compared with nonserious) offenses. However, with respect to property offenses this is not the case. In fact, the opposite is true; i.e., the differential is greater for nonserious property offenses.

When unadjusted item scores are used, there are no significant class by race interactions on any of the self-reported delinquency scales. With the transformation to standard item scores, a significant class by race interaction is observed on the predatory crimes against persons measure. The results of the two-way analysis of variance are presented in Table 4.

Table 4. Two-Way Analysis of Variance: Mean Predatory Crimes Against Persons Scale Scores (Standardized) by Race and Class

	CLASS		
RACE	Lower	Working	Middle
White	.013	−.030	−.267
Black	.828	−.253	−.143

Main Effects	Sum of Squares	DF	F	Significance Level
Race	39.818	1	6.256	≤.01
Class	45.149	2	3.547	≤.03
Interaction				
Race x Class	40.944	2	3.216	≤.04

Main effects are observed for both race and class. For whites, the major class difference is between middle-class youth and others (as was the case with unadjusted frequency scores). For blacks, the differences between lower-, working-, and middle-class youth are relatively greater, but the major difference is between lower-class youth and others. Working-class black youth report relatively fewer offenses against persons than do middle-class blacks, but this difference is not great. The interaction effect appears to be primarily the result of the relatively higher mean score for lower-class black youth. This analysis suggests a relatively high involvement of lower-class black youth in serious offenses against persons.

IMPLICATIONS OF FINDINGS

Item Selection and Response Sets

Three major points need to be considered relative to the selection and analysis of items in a self-report measure. First, it is critical that the items selected be representative of the offense areas to be covered. Special attention should be directed to this selection process, since the inclusion (or exclusion) of specific items appears to have implications for research findings, at least with regard to the social correlates of delinquent behavior.

Second, when attempting to make incidence estimates, it is important that response sets reflect the total frequency range. In this study, significant class and race differences were found only at the high end of the frequency range and, in most cases, would not have been observed had the traditional response sets been employed.

Third, from both theoretical and epidemiological perspectives, there is a danger in summarizing items into general categories. The present data indicate that using summary measures may obscure important differences by type of offense, and suggest that a more accurate picture is obtained by employing offense specific as well as summary measure analyses.[15]

It seems clear, from our data presentation and discussion, that the criticism of many SRD measures is well-founded; and, further, that generalizations about the social correlates of "delinquent behavior" as derived from measures with a limited response set and item representativity may be very misleading and are probably unwarranted. In addition, the way in which specific items are combined into summary measures has some bearing upon outcomes, and caution must be exercised in the interpretation of general summary measures.

Relationship between SRD and Official Data

In sum, it appears likely that the differences between the findings reported here and those from earlier self-report studies are, in fact, the result of differences in the specific SRD measures employed. The findings also suggest a logical connection between self-report and official measures of delinquency which, at least in part, accounts for the observed differences in the class and race distributions of these two measures.

The consistent findings of earlier self-report studies have led many sociologists and criminologists to the conclusion that race and class differences in arrests are primarily the result of processing biases and have little or no basis in behavior (Turk, 1969; Quinney, 1970; Williams and Gold, 1972; Taylor et al., 1974). The findings from the 1977 National Youth Survey suggest some behavioral basis for the observed class and race differences in official processing. In this sense, the National Youth Survey data are more consistent with official arrest data than are data from most prior self-report studies.

Further, these findings provide some insight into the mechanism whereby official actions produce exaggerated race and class (as well as age and sex) differences in delinquent behavior when compared with self-reported differences in normal adolescent populations. On both logical and empirical grounds, it seems reasonable to argue that the more frequent and serious offenders are more likely to be arrested (Short and Nye, 1957–1958; Erickson and Empey, 1963; Illinois Institute for Juvenile Research, 1973; Elliott and Voss, 1974; Empey, 1978), and that the youth population represented in official police statistics is not a representative sample of all youth.

Self-report studies are capturing a broader range of persons and levels of involvement in delinquent behavior than are official arrest statistics. Virtually all youth report some delinquent activity on self-report measures, but for the vast majority the offenses are neither very frequent nor very serious. Police contacts, on the other hand, are most likely to concern youth who are involved in either very serious or very frequent delinquent acts. Police contacts with youth thus involve a more restricted segment of the general youth population.

The findings discussed previously indicate that race and class differences are more extreme at the high end of the frequency continuum, that part of the delinquency continuum where police contacts are more likely.[16] In fact, at this end of the frequency continuum, self-report and official correlates of delinquent behavior are relatively similar. While we do not deny the existence of official processing biases, it does appear that official correlates of delinquency also reflect real differences in the frequency and seriousness of delinquent acts.

The results of this self-report delinquency study also have implications for previous tests of theoretical propositions which used SRD data. Stated simply, earlier self-report measures may not have been sensitive enough to capture the theoretically important differences in delinquency involvement. Given the truncated frequency distributions and the restricted behavioral range of earlier self-report measures, the only distinctions possible were fine gradations between relatively nondelinquent youth.

---

[15] While summary measures are reported herein, offense-specific analyses were presented in a previous paper (Ageton and Elliott, 1978).

[16] Although we have not presented the data here, age and sex differences are also greater at the high end of the SRD frequency continuum.

For example, earlier distinctions were typically among (1) youth with no reported offenses; (2) those with one or two offenses; and (3) those with three or more offenses. Given the extensive frequency distribution observed in this study, there is reason to question whether or not such a trichotomy would capture meaningful distinctions among offending youth. The most significant difference may not be between the nonoffender and the one-time offender, or even between the one-time and multiple-time offender. Equal or greater significance may be found between those reporting over (or under) 25 nonserious offenses, or between those reporting over (or under) five serious offenses.[17]

The ability to discriminate more fully among many levels and types of involvement in delinquent behavior introduces much more variance into the delinquency measure. That ability also allows for the identification of more extreme groups of offenders, and that identification may be particularly relevant for tests of theoretical propositions.

APPENDIX A

SELF-REPORTED DELINQUENCY AND DRUG-USE ITEMS AS EMPLOYED IN THE NATIONAL YOUTH SURVEY

How many times in the last year have you:

1. purposely damaged or destroyed property belonging to your *parents* or other family *members*.
2. purposely damaged or destroyed property belonging to a *school*.
3. purposely damaged or destroyed *other property* that did not belong to you (not counting family or school property).
4. stolen (or tried to steal) a *motor vehicle*, such as a car or motorcycle.
5. stolen (or tried to steal) something worth more than $50.
6. knowingly bought, sold or held stolen goods (or tried to do any of these things).
7. thrown objects (such as rocks, snowballs, or bottles) at cars or people.
8. run away from home.
9. lied about your age to gain entrance or to purchase something; for example, lying about your age to buy liquor or get into a movie.
10. carried a hidden weapon other than a plain pocket knife.
11. stolen (or tried to steal) things worth $5 or less.
12. attacked someone with the idea of seriously hurting or killing him/her.
13. been paid for having sexual relations with someone.
14. had sexual intercourse with a person of the opposite sex other than your wife/husband.
15. been involved in gang fights.
16. sold marijuana or hashish ("pot," "grass," "hash").
17. cheated on school tests.
18. hitchhiked where it was illegal to do so.
19. stolen money or other things from your *parents* or *other members of your family*.
20. hit (or threatened to hit) a *teacher* or other adult at school.
21. hit (or threatened to hit) one of your *parents*.
22. hit (or threatened to hit) other *students*.
23. been loud, rowdy, or unruly in a public place (disorderly conduct).
24. sold hard drugs, such as heroin, cocaine, and LSD.
25. taken a vehicle for a ride (drive) without the owner's permission.
26. bought or provided liquor for a minor.
27. had (or tried to have) sexual relations with someone against their will.
28. used force (strong-arm methods) to get money or things from other *students*.
29. used force (strong-arm methods) to get money or things from a *teacher* or other adult at school.
30. used force (strong-arm methods) to get money or things from *other people* (not students or teachers).
31. avoided paying for such things as movies, bus or subway rides, and food.
32. been drunk in a public place.
33. stolen (or tried to steal) things worth between $5 and $50.
34. stolen (or tried to steal) something at school, such as someone's coat from a classroom, locker, or cafeteria, or a book from the library.
35. broken into a building or vehicle (or tried to break in) to steal something or just to look around.
36. begged for money or things from strangers.
37. skipped classes without an excuse.
38. failed to return extra change that a cashier gave you by mistake.
39. been suspended from school.
40. made obscene telephone calls, such as calling someone and saying dirty things.

How often in the last year have you used:

41. alcoholic beverages (beer, wine and hard liquor).
42. marijuana—hashish ("grass," "pot," "hash").

---

[17] For example: for 1976, 5–10% of the most frequent offenders reported over 200 total offenses each, including over 30 serious offenses against persons.

43. hallucinogens ("LSD," "Mescaline," "Peyote," "Acid").
44. amphetamines ("Uppers," "Speed," "Whites").
45. barbiturates ("Downers," "Reds").
46. heroin ("Horse," "Smack").
47. cocaine ("Coke").

RESEARCH NOTES

THE GEOGRAPHY OF SOVIET CRIMINALITY*

LOUISE SHELLEY
American University

American Sociological Review 1980, Vol. 45 (February):111–122

A distinct geographical distribution of criminality exists in the Soviet Union as a result of the measures of social control exercised over the mobility and residence of the population, and that differentiates Soviet crime from that of both developing and developed countries. In the USSR increasing urbanization is not correlated with higher rates of criminality. As a result of the internal passport system and the difficulties of moving to large cities, the rates of criminality in the Soviet Union have shifted from the most populous cities of the USSR to the newly established cities of the far eastern and far northern parts of the USSR and to the rapidly expanding smaller urban centers.

INTRODUCTION

This paper attempts to analyze the geographical distribution of Soviet criminality which results from the measures of social control exercised over the mobility and residence of the population and which differentiates Soviet crimes from that of both developing and developed countries. This paper does not attempt a general overview of the problems of Soviet criminality and for that purpose the author recommends *Deviance in Soviet Society* (Connor, 1972).

This analysis is based on a year and a half's study in the Soviet Union, extensive reading of both published and classified Soviet criminological scholarship, and conversation with numerous scholars in the USSR. The conclusions reached in this article regarding the effect of population controls on crime are the author's own. Soviet scholars are incapable of reaching such conclusions because of a combination of ideological and intellectual constraints. This dual limitation exists because comments on internal population controls by Soviet scholars would be interpreted as criticism of the regime. Because Soviet scholars lack knowledge of the crime patterns of other societies or of the uniqueness of their own demographic controls—knowledge that would enable them to evaluate the effect of these controls on the criminality of their society—they find it impossible to draw comparable conclusions. Although based entirely on data collected and analyzed by Soviet scholars, this article synthesizes their findings to provide conclusions not contained in their research.

Contemporary Soviet Crime Research

It is necessary to understand the nature and training of the Soviet criminological community before their data and research efforts are analyzed and interpreted. Criminological research in the USSR is conducted by a large group of scholars studying under many different auspices and under complex ideological constraints. The large community of criminal law scholars who analyze the dynamics of Soviet criminality receive supplementary education in social science methods prior to their initiation of criminological research (Solomon, 1978:33–41). They conduct research in order to provide information to decision-makers in government for the formulation of criminal and general social policy (Solomon, 1978:41–50).

The research for this paper was done while studying in the Soviet Union on IREX and Fulbright-Hays Fellowships.

A travel grant was provided by the American Sociological Association so that this paper could be presented at the World Congress of Sociology at Uppsala, Sweden, in 1978.

After a hiatus of twenty-five years of scholarship the small core of Soviet criminologists that reemerged to resume criminological research after Stalin's death has succeeded in training a new generation of researchers in problems of criminality (Solomon, 1974:132–5). While crime research first reemerged in the mid-1950s in Moscow, it has spread not only to the central and far eastern parts of the Russian republic but also to the Baltic republics and Ukraine as well. Criminology is taught in law schools throughout the country and an increasingly sophisticated group of researchers has emerged in the past decade.

Though Soviet criminologists are accorded considerable respect and influence in the USSR, crime researchers are still plagued by the problem of confidentiality of data. While older and established Soviet criminologists are allowed direct access to the data in the procurator's office (the procurator is responsible for the proper execution of the law from the stage of police investigation through the review of the sentence) (Hazard et al., 1969:64), and in police files, and are themselves permitted to collect their own research data at labor camps and other sites, younger scholars do not have the same degree of access to crime data or to the highly informative classified criminological research documents.

The older, respected criminological scholars (almost all Communist party members) are given ample access to primary research data, and their findings are used by policy-makers to a degree unknown in the United States (Solomon, 1978:107). Most of these influential criminologists are not university-based but are instead employed by research institutes affiliated with the Academy of Sciences, the Procuracy and the Ministry of Internal Affairs (MVD), or the police.

The preeminent criminological research institute in the Soviet Union for years was the All-Union Institute for the Prevention of Crime and the Elaboration of Preventative Measures under the auspices of the USSR Procuracy and the Supreme Court (Solomon, 1978:57). Many of the articles cited in this paper are based on research conducted during its prime. This institute has recently come under increasingly strict ideological control and consequently does not presently have the intellectual freedom to conduct much objective, analytical research. Its former place in criminological research has been increasingly assumed by the scholars at the MVD or at the police institute[1] who are provided significant financial incentives in order to produce necessary classified research. To do this, they are given unrestricted research access and intellectual freedom to make intelligent recommendations as the basis for policy planning.

The research of both the university and institute-based criminologists in the Soviet Union may not have the quantitative sophistication of that produced by their Western colleagues but their conclusions seem to be soundly based on the data available to them. Their analysis could, however, extend further than it does if researchers were able to apply more sophisticated quantitative techniques or had greater access to an international body of criminological scholarship. Because of obstacles to research, Soviet criminologists have developed the unusual ability (seemingly characteristic of social science researchers operating in closed societies) to synthesize information available to them through official data collecting channels with that which they obtain through their informal contacts with the police and courts. Their research conclusions are subsequently more authoritative than might be expected of scholars working in such an incapsulated and highly secretive research environment.

Crime Data Used

Soviet crime data are not published, but police and court statistics are made available to trusted researchers by the central offices of the police and the Procuracy. Available data share some of the same problems of comparable American data. Crime statistics collection is not centralized (Juviler, 1976:133) but provided by different local authorities that have a vested interest in proving their effectiveness in controlling crime to the Party bureaucracy. Therefore, Soviet police reduce the number of reported crimes to demonstrate their success in solving criminal cases.

---

[1] Private conversations with Soviet scholars.

The authors cited in this article not only had access to Soviet crime data, and confidential crime studies, but also had the ability to collect their own data. They use the data as indicators of national crime trends rather than as definitive statements of absolute crime rates. Authors in the Soviet publications mentioned base their analyses on national and regional crime figures. Many of the individual researchers base their scholarly conclusions not only on available crime data but also on studies of populations of both prisons and labor camps, and studies of released convicts, thereby providing increased verification for their conclusions.

Crime data in the USSR do not have the reliability of statistics of smaller homogeneous societies that do not share the Soviet ideological commitment to the elimination of criminality. Yet, Soviet scholars are aware of the limitations of these data and use them with caution and conduct corroborating studies whenever feasible. The data referred to in their articles are based on some of the finest of contemporary Soviet crime research. Almost all the work cited here is unclassified and is available in Soviet libraries.

The following analysis will focus on the laws and policies that affect population residence and the subsequent effect they have had on the geographical distribution of Soviet crime. Geographical distribution will be examined in terms of rural and urban differences, and the impact of migration on crime.

Laws and Policies Affecting Residence in the Soviet Union

Passport regulations and population policies govern the lives of all Soviet citizens. These laws and policies determine the stability and size of the population in different regions of the country as well as the internal mobility of all citizens of the USSR. By controlling travel and residence within the country, Soviet authorities are able incidentally to influence the distribution of criminality within the country. The complex regulations governing the mobility of the Soviet population have resulted in a geography of crime that is different from that of other countries of similar economic and social development.

The residence of Soviet citizens is determined by a complex combination of birthplace, the internal passport system, marriage, and employment opportunities. There is no easy mobility between different settlements and cities in the Soviet Union. A Soviet citizen may spend his entire life in the same community if marriage or a job do not permit him to change his place of residence.

The internal passport carried at all times by Soviet citizens has been in existence since 1932. Before that time, Soviet citizens could generally reside in a city or town of their choice and could travel freely internally without documents. The internal passport received now by all Soviet citizens at age sixteen, with the exception of collective farm workers who are recently eligible (Matthews, 1972:53–4), indicates the individual's street address and town or village of residence, the only place where the holder of the passport may legally reside.

The internal passport controls mobility as well as residence; it is required to purchase plane tickets, long distance train tickets, and a room in a hotel. Individuals without passports are restricted exclusively to local travel. Therefore, the necessity of constantly showing a passport impedes the travel of wanted criminals.

> The passport is issued by the local police and is updated periodically. If the holder wishes to change his place of residence permanently he must get the formal permission of the militia in his chosen area before he moves in. This is only a formality in small towns and the less desirable spots where there is little pressure on public amenities, but may present a major difficulty in places like Moscow, Leningrad and republican capitals, which have more to offer their inhabitants. It is no secret that outsiders are all but excluded from permanent residence in Mos-

> cow, for example, some people find that registration there can be procured only by bribery. (Matthews, 1972:54)

As a result of the difficulties of migrating to a major city, the large number of internal migrants settle in the small and medium-sized towns in geographically remote areas where they can easily obtain residence permission from the police (Matthews, 1972:53–4). Permission to live in the major cities is secured only through employment there or marriage to a resident. High party and cultural positions and jobs in the police and secret police are among the categories of employment that carry with them permission to live in a major urban center such as Moscow, Leningrad, or Kiev.

Mobility for collective workers who do not possess internal passports is much more complex. They need to obtain a pass from the local village council to go anywhere for more than a month (Matthews, 1972:54). Permanent withdrawal from a collective farm and transfer to an urban setting is even more difficult. Many young male peasants who choose to leave collective farms never return to the village thereafter and enter their army service directly after high school. After army service, they move to construction sites in the far east and far north where they receive internal passports. With this document they can register permanently in a town or medium-sized city.

The low priority given to agriculture by Soviet authorities, combined with limited access to major urban settlements, causes the large number of migrants to settle in smaller cities with less desirable locations. The influx of many rural migrants with little training for urban life results in severe disorientation and high rates of criminality. The Soviet passport system has both negative and positive effects on the crime rates. While the settlement policies result in high rates of criminality in certain areas, the restrictions on internal mobility increase the certainty of detection.

The internal mobility and possible residences of former criminals are even more limited than those of ordinary citizens. All previous residences are recorded on the internal passport, including time spent in labor camp or prison (Lipson and Chalidze, 1977:175). Criminals from major urban centers, such as Moscow, who have served sentences of at least five years automatically lose the right to register at their former residence upon their return from labor camp or prison, a policy in effect since the 1920s (Gernet, 1927:160). Exceptions to this rule can be granted by the local police but these are rarely provided, and the police sometimes refuse to register those who have served sentences of less than five years.

The offender convicted of a major offense is severely limited in his choice of residence upon termination of his sentence. Individuals who are especially dangerous recidivists (convicted at least four times) and individuals convicted of armed robbery, serious assaults against the person, group rape, and premeditated murder as well as many crimes against the state and economic order "are not to be granted residence permits in cities, districts and regions listed in decisions of the Soviet government until the cancellation or annulment through established procedure of their record of conviction" (Lipson and Chalidze, 1977:185). Individuals not permitted residence in these areas cannot be "employed by enterprises, institutions and organizations located in those areas" (Lipson and Chalidze, 1977:186). Minors, serious invalids, pensioners, and women with young children are exempted from these orders. Exceptions can be made to these restrictions only with the "permission of Ministries of Internal Affairs of union and autonomous republics, Boards of Internal Affairs of krai ("territory") and oblast' ("region") Executive Committees of Soviets of Workers' Deputies" (Lipson and Chalidze, 1977:186).

Serious offenders and recidivists are thus denied the right to return to major cities or reside in the surrounding communities. As a result, the major urban centers house few experienced criminals and cannot serve as schools for youthful offenders. Medium-sized cities, on the other hand, are recipients of a disproportionate number of first-time serious offenders and recidivists.

The internal passport policies distort the usual distribution of criminality in an industrialized country. Major cities have comparatively low rates of criminality while smaller cities in undesirable locations contain a disproportionate number of past and current offenders. Soviet population policies and the internal passport system have shifted the distribution of Soviet crime away from the highly populated western cities of the RSFSR (Russian Soviet Federated Socialist Republic, the largest of the fifteen Soviet republics) to the more urbanized Baltic republics and to the far eastern and far northern administrative districts, primarily within the RSFSR.

RURAL CRIME

The rural farm areas of the Soviet Union have the lowest level of criminality in the country. This is explained by the population structure of collective and state farms, and the low economic priority given Soviet agriculture by Soviet policy makers, as well as by the traditional patterns of rural life and the inaccessibility of the Soviet countryside.

Soviet agricultural workers are employed either on state or collective farms. On state farms, workers are paid a monthly wage for their labor and have internal passports that permit them to travel freely within the country. Workers on collective farms share in the farm's profits and have no internal passports, thus denying them the right to travel without specially obtained permission. As a result, collective farm workers earn less than state farm workers and have virtually no opportunity for internal travel within the USSR. Collective farms are the predominant form of agricultural enterprise in the Soviet Union.

The combination of low wages, hard work, and absence of internal passports makes life on collective farms very undesirable. The male population on Soviet farms, already reduced by great Soviet casualties during World War II, has been further decimated by the sizable exodus of Russian youth and other Slavic nationalities from rural areas. This internal migration will be discussed in greater depth later in this paper. The general absence of men, who are responsible for over 85% of Soviet criminality (Solopanov and Kvashis, 1971:6), from collective and state farms and the disproportionate representation of older women help explain the low rate of criminality in the Soviet countryside.

Traditional patterns of rural life also contribute to the low level of criminality. Crime has traditionally been lower in rural areas because of the tight social controls exerted by members of the rural community on each other and the general economic homogeneity of rural inhabitants. Informal social controls in rural life are still significant in preventing criminality, and rural inhabitants cooperate with the police in reporting crimes.

The inaccessibility of the Soviet countryside contributes significantly to the low rate of rural criminality by deterring nonnative criminals from wandering into rural areas. As the few privately owned cars are possessed almost entirely by the Soviet elite, the minimal public transportation in rural areas and the poor condition of rural roads minimize access to the countryside and curtail the possibility of preparation of crimes by nonresidents. The limited possessions of rural residents and the difficulties in reaching and escaping from rural areas compound the improbability that urban dwellers will commit crimes in the countryside.

Theft of government and social property, violent crimes and *samogon* ("the production and sale of home-brew") have traditionally been the characteristic forms of criminality in the rural parts of the Soviet Union (Lichnost' Prestupnika, 1971:96–7). Theft of government and social property remains the predominant form of rural theft. Rural inhabitants continue theft of government and state property to the degree that they did in the 1930s. Rural residents 40 years ago comprised two-thirds of the Soviet population and were responsible for 62% of the crimes committed in this category, while 30 years later the 45% of the Soviet population residing in rural areas committed 42% of the offenses in this category (Lichnost' Prestupnika, 1971:86; Naradnoe Khoziaistvo, 1969:7).

Violent crime in the last century was, disproportionately, a rural phenomenon. By the 1920s, urban dwellers were responsible for more violent crime than their proportional representation in the population. With the continued exodus of young males from rural areas, there has been a further reduction in the level of rural violence. While violent crime is still more common in rural areas than crimes against personal property (Lichnost' Prestupnika, 1971:114), the traditional rural propensity toward violent crimes is not as marked as a century ago.

Bootlegging is the only traditionally rural crime that continues on a mass scale. This offense, traditionally the domain of older women, has been the most common female offense since the pre-Revolutionary period (Gernet, 1924:185–6). Women with limited financial resources resulting from low monthly salaries or even lower retirement pensions (sometimes as little as $25 a month) turn to this form of criminality as an easy means of increasing their incomes.

Soviet agricultural and manpower policies have caused a dramatic decline in the level of criminality in the countryside and an increase in crime in areas of recent settlement by formerly rural inhabitants. Traditional forms of criminality are no longer characteristic of the rural environment though traditional methods of peasant social control still prevail.

MIGRATION AND CRIME

The relationship of migration and criminality is currently a subject of great scholarly interest in the Soviet Union. The annual migration of 4–6% of the population, approximately 8,000,000 people, represents a cumulative problem of significant proportions (Babaev, 1974:9). The severe adjustment problems of migrants that often result in criminality have become a subject of concern to Soviet policymakers and researchers.

The rate of urban growth of medium-sized cities in the past two decades has been sizable. Between 1959 and 1970, the number of cities with populations of over 100,000 increased by 73 (Sokolov, 1973:150). The migration that has occurred has resulted primarily from the migration of young males aged 16–29 into urban areas. The movement of these young people has been of such proportions that it has measurably reduced the average age of the urban population (Sokolov, 1973:153). Soviet criminologists have closely monitored the effect of this most potentially active criminal group on recorded rates of criminality in urban areas. They have concluded, based on detailed sophisticated studies, that there is a strong correlation between the increase in internal migration and a recorded increase in urban crime, They anticipate that with further growth in cities there will be a still further rise in recorded crime rates (Sokolov, 1973:152).

Soviet researchers studying crime in the RSFSR have learned that a region with a high coefficient of migrants is characterized by a higher coefficient of crime (Babaev, 1968:86). This observation reflects the problem that migrants, primarily individuals of rural background, find difficulty in making the adjustment to an urbanized or culturally different environment far removed from their family and their rural traditions. These recent migrants face the basic problem of acclimatizing themselves to the absence of controls in their impersonal new place of residence while all their lives they have been accustomed to the strict social controls of their traditional rural communities.

There are two fundamental types of internal migration in the Soviet Union. Rural migrants move either to heavily populated regions or to lightly populated areas that Soviet authorities believe would benefit from an increase in population (Babaev, 1968:86–7). Each of these types of moves involves its own problems of adjustment and its own potential for criminality.

Movement to an already inhabited region requires migrants to adjust to already established cultural and social patterns. After their arrival in Soviet cities, individuals from rural areas, unacquainted with urban ways, have difficulty in locating housing and proper employment (Babaev, 1968:87). During the strenuous period of acclimation, migrants frequently face difficult situations that sometimes resolve themselves in acts of criminality.

Migration to a previously lightly inhabited region brings with it a different array of problems. Rural Russian migrants are frequently assigned residences in other republics or in different areas of the Russian republic with non-Slavic inhabitants of totally different cultural, linguistic and ethnic backgrounds (Babaev, 1968:87). These migrants, who have never previously been exposed to individuals of different cultures, suffer many of the consequences of culture conflict described by Thorsten Sellin (1938:63–70). The conflicting norms of the Russian migrants and the native inhabitants frequently result in violent conflicts and other criminal acts. While Soviet authorities comment that Russian influx into traditionally Moslem areas sometimes has the beneficial effect of reducing criminal vestiges of the past (for example, Soviet law outlaws traditional Moslem marriage and social practices), more often this severe dislocation has criminological consequences.

Soviet researchers have attempted to understand the effects of these two kinds of migration by analyzing population and crime trends in areas recently settled by migrants. The work conducted at the All-Union Institute for the Study of Crime and the Elaboration of Preventive Measures, under the auspices of the Soviet Procuracy, has been in progress for 15 years.

Two studies conducted by the Institute, the nation's leading center for criminological research, in the 1960s examined the relationship between population migration into different areas and the level of criminality. Data was collected on the level of population influx and crime rates for all the oblasts (major territorial subdivision directly below republic size) of the RSFSR and the autonomous republics of RSFSR, regions inhabited originally largely by non-Russian nationalities.

In 1968 seven of the eight oblasts with the greatest number of migrants (Tiumen, Magadan, Kamchatka, Yakutsk, Tuvin, Komi, Krasnoyarsk and Primorskii [coastal]) the rate of criminality was highest for the republic (Babaev, 1968:88). In the 20 oblasts with the least influx of population, 13 of the 20 regions were in the lower half of all RSFSR oblasts in their rates of criminality. The same relationship between patterns of criminality and migration were observed in an earlier study conducted between 1963 and 1965. All oblasts which had an observed decline in population had also experienced a reduction in the crime rate. This indicates that net emigration from a particular oblast' resulted in a lower rate of criminality, but an increase in population resulting from migration into a particular area was correlated with a concomitant increase in criminality (Babaev, 1968:88–9).

Babaev, previously a leading researcher of the Procuracy Institute on the subject of migration and crime, concludes from these results: "It is impossible to state that there are sufficient examples where the number of residents declined but crime was not reduced" (1968:88). Soviet statistics lead to the conclusion that the rate of crime per capita is reduced only when the population declines and there is no significant population migration into the area.

Migrants might arrive in a particular community either independently or under organizational sponsorship. The form in which they arrive and the size of the local population are significant in determining the effect of their migration on local crime rates. When large numbers of migrants arrive in one administrative region at the same time, they contribute a disproportionately large percentage of the total crime rate. However, when small groups arrive in a community their rates of criminality do not differ markedly from the rest of the population (Babaev, 1968:89). In 1966, in Novoselorskii and Birilusski regions, where large groups of migrants had arrived in large numbers, yet represented only a small proportion of the total population, they nevertheless contributed 33% and 30% of all criminals, respectively.

The social structure of a particular region is also important in explaining the impact of migrants on the local crime rate. The crime situation of Sakhalin oblast' and Yakutsk ASSR is used by Soviet authorities to show the impact of community composition and social services on the dynamics of criminality. Yakutsk, with nearly 50% of its population residing in rural areas, was ill-prepared for the influx of large numbers of recent migrants. This is demonstrated by the fact that, in the years 1963–66, urbanized Sakhalin with 13% more population than Yakutsk (SSSR Administrativno-territorial'noe delenie, 1963:66) had an approximately equal number of known offenses (Babaev, 1968:89). Prior urbanization and community preparedness help reduce some of the negative consequences of intense population migration to a particular area.

More recent research has been done by Babaev on the social surroundings and personalities of criminals who were migrants or who were permanent residents. The study was based on 1,000 inmates in labor camps housing criminals of differing degrees of severity of criminal acts. Of the subjects in the study, 15.3% were migrants—had not lived in their previous location for more than one year—and the remaining 84.7% were permanent residents (Babaev and Antonian, 1975:5). For research purposes the migrants were divided into those who had been residents for more than six months and those who had lived at their last location for less than six months.

In almost all categories, significant differences were found between those who were permanent residents and those who were migrants. Forty-two percent of the permanent residents were married while 75% of the migrants were single (Babaev and Antonian, 1975:7). Thirty-eight percent of the new settlers lived with their parents while 57% of the permanent residents who were in labor camps had resided with their parents. Eight percent of the new settlers lived with their spouses while 30% more of the permanent residents lived with their families. The researchers concluded that the separation of the migrants from parents and family had a negative effect on rates of criminality (Babaev and Antonian, 1975:13).

The migrants had considerably worse housing conditions than the permanent residents. Thirty-eight percent of the migrants lived in their own apartment or house while an additional 35% of the permanent residents enjoyed such living conditions. Thirty-two percent of the migrants of at least six-month longevity and 30% of the most recent arrivals resided in dormitories at the time they committed their offense (Babaev and Antonian, 1975:12). It is evident that the inferior quality of residential accommodations has a direct effect on the increased tendency to commit crime.

The criminologists, like the demographers, found that the migrants had a higher educational level than the permanent population. Only 4% of the most recent migrants had only a fourth-grade education while the corresponding figures for the less recent arrivals and permanent residents was 12% and 10%, respectively. The same relationship held true at all other educational levels as well. Sixty-eight percent of the most recent migrants had finished 5–9 years of school (there are 10 grades in the Soviet educational system) while the comparable figure for the permanent residents was 63% and for the recent settlers 58% (Zaionchovskaya, 1972:105–8). At the high school and college level, migrants and recent settlers again outstripped the resident population. Thirty percent of the first group, as opposed to 26% of the second level, completed high school or had received some college education (Babaev and Antonian, 1975:6–7). The fact that the migrants had such educational advantages and still lapsed into criminality indicates that the better jobs and higher wages available to the migrants as a result of their superior training did not act as a sufficient deterrent to their criminality. The problems of the migrants' adjustment were of such magnitude as to outweigh the financial and employment advantages of their new environment.

The migrants also had distinguished themselves by the high percentage that had previous convictions. Eighty-two percent of the migrants surveyed in labor camps had previous convictions while comparable figures for the most recent arrivals and the permanent residents were 76% and 59%, respectively (Babaev and Antonian, 1975:8). These patterns of previous criminality were further supported by the association patterns of the migrants. Both categories of migrants were much more likely to associate regularly with individuals with prior convictions. These associations were developed at the migrants' place of residence (Babaev and Antonian, 1975:16–17).

The results indicate that despite the initial training and educational advantage possessed by the migrants, their living conditions, removal from their families and patterns of association all contributed to their disproportionately high rate of criminality. The number of migrants arriving in a community at a particular time and the extent to which they are absorbed into their new place of residence are reflected in their rates of criminality.

While the increased criminality of rural migrants in a new unfamiliar urban environment is an internationally known problem, the Soviet case differs significantly from that of other societies. The rural emigrants eager to leave the collective and state farms are denied access to the largest cities in the Soviet Union. Therefore, these young men settle either in medium-sized cities or relatively unsettled culturally different regions. In both cases, these young, frequently unattached men in the age most likely to commit offenses face serious adjustment problems that frequently result in the commission of crimes.

The migrants commit a significant proportion of the crime recorded in medium-sized cities. As a result, unlike the other industrialized and industrializing countries, the Soviet Union is experiencing its most severe growth in criminality not in the large but in the medium-sized cities of the USSR. Soviet residential policies have resulted in a geographical distribution of crime in the USSR that is significantly different from that of other countries of similar economic and social development.

URBAN CRIME

International statistics demonstrate that the greater the degree of urbanization of a country, the higher the level of criminality. The Soviet Union also conforms to the internationally established correlation between the level of urbanization and the recorded crime rates. In the years 1963–66, the ten republics with the highest levels of crime are regions with the highest levels of urbanization. Estonia and Latvia, both republics with high rates of criminality, are 65% and 62% urbanized, respectively (Sokolov, 1973:51).

The intensive influx into urban areas that began during the Krushchev period continues to the present. As was previously mentioned, most of the migration is into newly built cities (Babaev, 1972:98) because entry into the larger, more established cities is much more difficult for all potential migrants. During this period Voronezh and Tula, medium-sized Russian cities, grew by 73% and 78%, respectively, and the capital of Estonia grew by 86%, while the larger capital of the Ukraine, Kiev, experienced only a growth of 60% during these years (Babaev, 1968:89). Between 1959 and 1970 there was an overall growth in the urban population of 36 million (Babaev, 1972:100). As the urban population in the Soviet Union rose to 136 million in 1970, during the same eleven-year period the number of rural and small-town residents declined markedly. The number of cities with populations larger than 50,000 rose from 304 to 409 (Babaev, 1972:100).

In almost all cases this population influx had a negative effect on recorded rates of criminality. Recorded increases in crime as a result of increasing population were observed not only in the western parts of the RSFSR but in far eastern RSFSR, in the far east, eastern and western Siberia, in the Baltic republics of Estonia and Latvia, and in the Slavic republic of Byelorussia. In one urbanized region of Byelorussia where the population increased by two-thirds in ten years, the crime rate grew at a rate greater than that of the population. The criminal justice system did not keep pace with the growth in crime; while the recorded number of offenses in the Lidsko region increased significantly, the number of people brought to trial did not rise proportionately (Kondrashkov, 1966:38).

The highest recorded rates of criminality in the Soviet Union are not found in the largest cities, as in the United States, but are found in the medium-sized cities. Kiev and Leningrad, cities with low rates of population growth, have lower crime rates than Tobolsk which has grown rapidly in recent years (Babaev, 1972:98). The stability of a city's population and not its size appears to be the more significant factor in determining the rate of criminality in the USSR. Vladivostok, the city with the highest recorded crime rates in the Soviet Union,[2] though a large city, is a port with a highly transient population—a fact which appears to account for the high rate of street crime.

While crime in western Europe and the United States is greatest in the largest cities and less in medium-sized cities, this relationship does not hold true in the Soviet Union. The largest cities of the Soviet Union—Moscow, Leningrad and Kiev—have much lower recorded conviction rates than the national average, and lower rates of criminality than the more newly formed cities with smaller populations (see Table 1) (Kuznetsova, 1971; Ostroumov, 1970; Babaev, 1972; Sokolov, 1973). The high crime rates in these medium-sized cities can be attributed to the mass of migrants unaccustomed to urban life.

Table 1. Conviction Rates for American and Soviet Cities and the USSR

	(Rate per 100,000) Conviction Rate
1) Soviet cities over 1.5 million[a] (Moscow, Leningrad, Kiev)	442
2) Cities with population under 0.5 million[b] (Tobolsk, Tartu, Vladivostok, secondary cities of Latvia)	500
3) American Cities[c] (2,925 cities with total population of 39 million)	2573
4) USSR (National average, 1976)[d]	1045

Sources: [a] Derived from selected crime statistics (Kuznetsova, 1971). The total conviction rate is based on an extrapolation of these statistics, using the overall distribution of crime, by category of offense (Ostroumov, 1970:248). This also includes information in Babaev (1972).

[b] Derived from information in Sokolov (1973) and from private sources with access to Soviet criminal statistics.

[c] Derived from Table 5.13, Disposition of persons formally charged by the police, 1975 (U.S. Department of Justice, 1977:541).

[d] Derived from Neznansky (1979:47).

Soviet researchers have not only examined overall trends towards urbanization but have studied the dynamics of criminality within the urban environment. Soviet research findings conform with those of Polish researchers who discovered a concentration of crime in certain regions of a city. Such research was replicated in the Russian city of Orel in 1971.

The researchers divided the city into three regions, but in the report of their findings they did not explain how these subdivisions of Orel were selected. The three regions were analyzed in terms of their indices of crime, recidivism, dangerous criminality and the retention rate of individuals on charges of petty hooliganism. One of the three regions scored highest in terms of all indicators while the third region had the lowest index in three of the four categories analyzed. The offenders did not often commit their crimes near their places of residence but, rather, in different regions of the city (Mogilevskii and Suslov, 1973:114).

Similar statistics have been collected for Moscow as well as for other Soviet cities and reveal the same localization of crime in certain regions of each city. In Moscow, recent studies have shown that crime is concentrated in the older sections of the city that have traditionally had high rates of criminality and in the new regions of the city that house workers who have only recently emigrated from the countryside. Many cities have established such internal maps of the distribution of criminality but they are not always based on methodologically sound criminological research (Mogilevskii and Suslov, 1973:114).

These studies of the distribution of criminality within the urban environment are performed to understand the social forces that influence crime and to correlate the level of criminality with other forms of deviant behavior, such as alcoholism and suicide. By determining the regions of greatest social instability, Soviet scholars hope to localize the urban regions in need of social and community help (Mogilevskii and Suslov, 1973:115).

[2] Soviet dissertation defense at the Criminal Law Department, Law Faculty, Moscow State University, Moscow, Spring, 1975.

Suburbia, consisting of prosperous residences surrounding major urban centers as they exist in the United States and much of western and eastern Europe, are unknown in the Soviet Union. The residential areas surrounding Soviet cities are inhabited by young workers and their families who could not obtain residential permits to live in the major cities. There is a high rate of criminality among young workers who commute lengthy hours to their schools and jobs in the city. Criminologists have called for increased social control of the mobility of these youth in the outlying urban areas.

An interesting study of these youthful commuters was conducted over a decade ago in Leningrad. Through their statistical studies, researchers confirmed their hypothesis that the percentage of persons aged 15–18 committing crime was higher among those who commuted to work and study in Leningrad than those who resided near their schools and places of residence. This difference in levels of criminality of the two groups was even higher than anticipated (Derviz, 1971:65).

The crime committed by these youthful offenders was not associated with their places of residence or work but was a result of their daily four-hour commutation that removed them from parental control and provided time for gambling and drinking. Study during their hours of commutation was impossible because of the noise, poor light, and poor ventilation on the commuter trains (Derviz, 1971:66). Researchers noted a much earlier age of entry into sexual relations, a much higher rate of alcohol use, and a much larger influence of adult criminals (Derviz, 1971:68) on these individuals than on youths residing within the city limits.

During their long hours of transit, the youthful commuters made the acquaintance of drunks, parasites, and recidivists. These undesirable individuals had a strong influence on the young potential criminals as reflected in the fact that 25–30% of these minor-age suburban Leningraders committed their crimes under the direction or provocation of adults (Derviz, 1971:67). The crime problem of these youthful offenders was so great that they were responsible for much of the crime committed by minors within the city of Leningrad (Derviz, 1971:70).

This initial study of the crime of youthful commuters in Leningrad has led to further research in this area. The problem observed in Leningrad is not local but is a growing problem in the Soviet Union as more individuals (because of the passport system and the limitation on growth of cities) settle in the outlying urban areas and are forced to commute long distances to work and school.

CONCLUSION

The passport system and the difficulties of moving to large cities have affected the Soviet crime problem in two ways. First, they have shifted the greatest degree of criminality away from the big cities of the Soviet Union to the newly established cities of the far east and the far north and to the rapidly expanding smaller urban centers. Second, the communities surrounding major cities are not the privileged retreat of the prosperous from urban problems but are the homes of young men who are forced to commute long hours, under unfavorable conditions, to their schools and jobs. However, their crimes are not committed in the suburbs, but in the urban communities to which they commute. The population controls and internal passport system in the USSR have resulted in a distribution of crime which is fundamentally different from that found in most industrialized countries.

This analysis of the geography of crime in the Soviet Union illustrates one of Durkheim's principles: "There is no occasion for self–congratulation when the crime rate drops noticeably below the average level, for we may be certain that this apparent progress is associated with some social disorder" (Durkheim, 1964:72). A reduction in the crime rate of major Soviet cities has been achieved only at the social cost of reducing personal freedom of movement and causing increased problems of criminality in more remote parts of the country.

ANALYZING COLLAPSED CONTINGENCY TABLES WITHOUT ACTUALLY COLLAPSING*

PAUL D. ALLISON
Cornell University

American Sociological Review 1980, Vol. 45 (February):123–130

For a variety of reasons, log-linear models are sometimes fit to "collapsed" contingency tables which sum over the categories of one or more variables in the original table. I show here that the same results can be readily obtained by fitting a log-linear model to the full table, without actually collapsing it. All that is necessary is to exclude certain parameters pertaining to the collapsed variable. This approach is particularly useful for the analysis of recursive systems of categorical variables.

There are several situations in which it is desirable to take a contingency table with a given number of cells and "collapse" it into a smaller contingency table by summing over some or all of the categories of one or more variables. It may be that some of the categories are thought to be theoretically or practically equivalent. Or perhaps one of the variables is considered to be irrelevant to the analysis at hand. Most importantly, collapsing is an essential feature of Goodman's (1973) method for the log-linear analysis of recursive systems of categorical variables.

For example, suppose we have four categorical variables—A, B, C, and D—and we assume that A is causally prior to B, C, and D; B is causally prior to C and D; and C is causally prior to D. Goodman proposes that one first analyze the four-way table, with D taken as the dependent variable. Then one collapses over D to obtain a three-way table, with C taken as the dependent variable. Finally, one collapses over C to study the effect of A on B.

There are disagreements as to the appropriateness of this method. Reynolds (1977) is troubled by the fact that significant associations can appear in the collapsed table even when there are no such associations in the full table, and suggests that this may produce misleading results. However, Gillespie (1978) and Goodman (1979) have countered that in a recursive system it is the collapsed table that more accurately describes the true causal structure. Thus, when looking at the effects of A and B on C, it is misleading to further cross-classify on a subsequent dependent variable D.

Let me emphasize at the outset that I completely agree with Goodman and Gillespie. There is simply no way to represent a recursive causal system by a single log-linear model for the full multiway table. The method of successive collapsings, on the other hand, seems entirely appropriate for such recursive systems.

Nevertheless, collapsing can be tedious, especially when the original table is large. Even when one has a computer program to do the collapsing, it can be inconvenient to shift back and forth between different collapsed tables. I will show here that, while the method of collapsing is a correct way to analyze recursive systems, it is not strictly necessary. One can obtain identical results by fitting a succession of models to the full multiway table. Not only does this reduce computation and increase flexibility, but it also offers important insights into the model itself. Further, this method—while especially useful for recursive systems—also has important implications for other situations in which collapsing seems desirable. The method is based on formal results obtained by Goodman (1971) and by Bishop et al. (1975), though they did not develop these particular implications in their work. I

Table 1. Attitudes toward Jobs for Blacks by Education, Region, and Year (Cell Frequencies)

		1946		1963	
		Attitude			
		Favorable	Unfavorable	Favorable	Unfavorable
South	Grade	52	206	71	44
	High	64	163	126	31
	College	42	51	55	14
Non-South	Grade	311	365	148	61
	High	439	374	410	56
	College	204	83	201	8

begin with an example but, further on, I will set down some general principles and indicate their mathematical justification.

The data to be analyzed consist of a four-way contingency table reported by Davis (1974), who adapted it from Schwartz (1967). The variables are year (1946, 1963), region (South, non-South), education (grade school, high school, college), and attitude toward jobs for blacks (favorable, unfavorable).[1] I will represent these variables by the letters A, B, C, and D, respectively, and I assume that they constitute a recursive causal system in which causal priority corresponds to alphabetical order. The table is reproduced here as Table 1.

Since the analysis of the four-way table, with D taken as dependent, is the same for both Goodman's method and the method proposed here, I do not report any of those results. Suppose, now, that we have already completed that analysis and we want to look at the effects of A and B on C. Goodman says to collapse the four-way table by summing over the categories of variable D to create a three-way table, ABC. Then, one can proceed to fit appropriate log-linear models to this collapsed table. Five models for the collapsed table are presented in Table 2A, along with their respective degrees of freedom and the likelihood ratio chi-square statistic (denoted by G^2).[2] The models are specified by the minimal set of marginal tables fitted to the data; but each of these marginal tables also corresponds to a set of parameters in the log-linear model. As is usual when one of the variables is taken to be dependent on the others, I have fitted the marginal table (AB) for the independent variables in each model. This ensures that the fitted model is equivalent to a logit model for the dependent variable. For further discussion of this point, see Fienberg (1977:79–81) or Gillespie (1978). A cursory examination of these models leads to the conclusion that model 2 is the simplest model that fits the data reasonably well. It says that A and B both have main effects on C, but there is no higher-order interaction.

Now, let us do it a different way. In Table 2B, I present results from fitting the same five models to the full four-way table. Since variable D is not included in any of the fitted marginal tables, this is equivalent to setting equal to zero all parameters pertaining to variable D in each of the fitted models. At first glance, the results seem to be markedly different. The chi-square statistics are all over 800, indicating that none of the five models fits the data well. However, a closer look reveals that *differences* in chi-square values for any two models are identical in Tables 2A and 2B, and that the same is true for differences in degrees of freedom. Moreover, since we know that the saturated model for the three-way table must have a chi-square of zero with zero degrees of freedom, we can use this as a baseline to recover the same chi-square values and degrees of freedom that we got in Table 2A. To accomplish this, we simply subtract the results for model 1 from the results for each of the succeeding models. This is shown in the last two columns of Table 2B.

---

[1] The last variable is the dichotomized response to the question, "Do you think Negroes should have as good a chance as white people to get any kind of job or do you think white people should have the first chance at any kind of job?"

[2] All models were fit by maximum-likelihood estimation using the program GLIM.

Table 2. Results from Fitting the Same Models to the Collapsed Table and to the Complete Table

A. Models Fitted to ABC Table

Fitted Marginals	G^2	d.f.
1. ABC	0	0
2. AB, AC, BC	2.4	2
3. AB, AC	21.4	4
4. AB, BC	72.9	4
5. AB, C	89.3	6

B. Models Fitted to ABCD Table

Fitted Marginals	G^2	d.f.	$G^2-863.0$	d.f.−12
1. ABC	863.0	12	0	0
2. AB, AC, BC	865.4	14	2.4	2
3. AB, AC	884.4	16	21.4	4
4. AB, BC	935.9	16	72.9	4
5. AB, C	952.3	18	89.3	6

These results demonstrate that we can easily fit models to collapsed tables without actually collapsing, and still get the same chi-squares. What about parameter estimates? These are also the same, even without any sort of adjustment. Table 3 gives estimated coefficients and their standardized values for model 2—the simplest model which fits the data—computed under both procedures.[3] The estimates are all identical—with the exception of the grand mean (or intercept) which has no substantive interpretation, anyway.

Table 3. Coefficient Estimates for Model 2 in Table 2*

Parameter	Estimate	Estimate/Standard Error
A	.366	4.49
B	−.997	−9.88
C1	.066	.75
C2	.826	10.65
A.B	−.216	−2.67
A.C1	.759	7.43
A.C2	.197	2.10
B.C1	.292	2.64
B.C2	−.074	−.69

* In the full table, the intercept is 4.62. In the collapsed table, the intercept is 5.31

To complete the example, let us examine the effect of variable A on variable B. Goodman says to collapse over both C and D and, then, to fit models to the two-way AB table. In Table 4, I have fitted both the saturated model (which allows for an effect of A on B) and the model of independence, which asserts that A has no effect on B. The model of independence can be rejected at the .05 level, and the estimated log-linear parameter for the effect of A on B is .17. Table 4 also displays results from fitting the same models to the full four-way table. The chi-squares are enormous, but the difference in chi-square (between the "saturated" model and the model of independence) is 4.5, the same as that in the

Table 4. Results from Fitting the Same Models to a Collapsed Table and to the Complete Table

Fitted Marginals	G^2	d.f.
Models for the AB Table:		
1. AB	0	0
2. A, B	4.5	1
Models for the ABCD Table:		
1. AB	1408.0	20
2. A, B	1412.5	21

---

[3] These estimates were produced by the program GLIM. Readers whose experience with programs for estimating log-linear models is limited to ECTA may find these estimates somewhat puzzling. Unlike ECTA, GLIM uses an algorithm known as iteratively reweighted least-squares which produces maximum-likelihood estimates equivalent to those produced by ECTA. However, GLIM uses a different parametrization of the model; whereas ECTA constrains the sums of certain parameters to be equal to zero, GLIM arbitrarily constrains one of the same set of parameters to be equal to zero (Holt, 1979). This difference is analogous to the difference between the parametrization of analysis of variance and the parametrization of multiple regression with a set of dummy variables as independent variables. Also, unlike ECTA, GLIM produces standard-error estimates for the parameters of unsaturated models which were used here to calculate standardized parameter values (each estimate is divided by its standard error). In spite of these differences, the point made by Table 3 is the same for GLIM or ECTA; you get the same parameter estimates whether you fit the model to the full table or to the collapsed table.

two-way table. The estimated parameter for the effect of A on B is also the same.

At this point, the general principle should be clear: to analyze a collapsed table without actually collapsing, simply fit to the full table the same marginal tables that you would have fitted to the collapsed table. The parameter estimates and their standard errors will be identical to those obtained from the collapsed table. The chi-square and the associated degrees of freedom will be higher; but differences in chi-square and degrees of freedom between models will be the same. To obtain the identical chi-square values, fit to the full table the "saturated" model for the collapsed table and then subtract its chi-square and degrees of freedom from those of the unsaturated models. Note that these results hold only for maximum likelihood estimates and for the likelihood ratio chi-square. For Pearson's goodness-of-fit chi-square, the equality will be only approximate.

Proof

At this point, the reader who is not interested in the mathematical detail may wish to skip ahead to the sections on additional applications. The equality of differences in chi-square is easily proved, using results in Goodman (1971). Consider models 1–5 in Table 2B. Goodman shows that the likelihood ratio chi-square for each of these models can be partitioned into two components: (a) the chi-square for testing the hypothesis that D is conditionally equiprobable, given variables A, B, and C; (b) the chi-square for a hypothesis about the ABC marginal table. The particular hypothesis tested in (b) corresponds to the fitted marginal tables. Since the component due to (a) is the same for all five models, it immediately follows that differences in chi-square must be equal to the differences in chi-square obtained by analyzing the ABC table directly. The generalization to higher-dimensioned tables is straightforward.

The equality of the estimated parameters is slightly more difficult to prove. Consider a three-way table for variables A, B and C. I will show that, if all parameters pertaining to variable C are set equal to zero, the estimated parameters pertaining to variables A and B are the same whether calculated from the three-way table or from the two-way table obtained by collapsing over variable C. First, some notations:

x_{ijk}—Observed cell frequency for level i of variable A, level j of B, and level k of C.

x_{ij+}—Observed cell frequency for table collapsed over C.

$\hat{m}_{ij}$—Maximum-likelihood estimate of expected cell frequency under a given model for the two-way table.

$\hat{m}_{ijk}$—Maximum-likelihood estimate of expected cell frequency under an equivalent model applied to the three-way table (all parameters pertaining to C must be set equal to 0).

$\hat{m}_{ij+}$—Frequencies obtained by collapsing $\hat{m}_{ijk}$ over C.

Estimated parameters are always algebraic functions of the estimated expected frequencies. What we have to show, therefore, is that the parameters obtained from $\hat{m}_{ijk}$ are the same as those obtained from $\hat{m}_{ij}$. The proof is in two steps. First, I show that the parameters obtained from $\hat{m}_{ijk}$ are the same as those obtained from $\hat{m}_{ij+}$. Then, I show that $\hat{m}_{ij+} = \hat{m}_{ij}$.

Step 1. In the table of frequencies, $\hat{m}_{ijk}$, C is independent of the variables A and B since we have explicitly set to zero all parameters linking C to A and B. We can therefore invoke the collapsibility theorem of Bishop et al. (1975:47), which says that if one set of variables is independent of another set, we can collapse over the first set without affecting the parameters pertaining to the second set. This means that we get the same estimated parameters from the $\hat{m}_{ij+}$ as from the $\hat{m}_{ijk}$.

Step 2. A basic property of maximum-likelihood estimation of log-linear models is that the estimated expected frequencies must sum to the fitted marginal tables (Bishop et al., 1975:69). Since we are fitting the same marginal tables to both the three-way and the two-way tables, obviously both $\hat{m}_{ijk}$ and $\hat{m}_{ij}$ must sum to the same marginal tables. It follows that $\hat{m}_{ij+}$ and $\hat{m}_{ij}$ must also sum to the same marginal tables. It is also the case (Bishop et al., 1975:69) that there can be only one set of estimated cell frequencies that both satisfies the internal constraints implied by the model and sums to the fitted marginals. Hence, $\hat{m}_{ij+} = \hat{m}_{ij}$.

This result is immediately generalizable to higher dimensional tables. Suppose we have a table for variables P, Q, R, S, and T and we wish to collapse over variables S and T. We can treat S and T as a single joint variable, C, and treat P and Q as a single joint variable, A. Letting R=B, we can apply the preceding proof directly.

Collapsing over Independent Variables

To this point, I have focused on the issue of collapsing over one or more dependent variables in a recursive system. These results also shed light on what it means to collapse over an independent variable. Consider, again, the example of a four-way table with variables A, B, C, and D and suppose that D is considered to be dependent on the other three variables in a logit-type model. In such a model, it is convenient to divide the log-linear parameters into two groups:

(a) Parameters that pertain to the dependent variable and its relationship with the independent variables;
(b) Parameters that pertain only to the independent variables and the relationships among them.

Although the parameters in group (b) are always estimated in a dependent variable model, they are not ordinarily of any substantive interest (Gillespie, 1978). This is because they measure relationships that are conditional on the levels of the dependent variable and, thus, have no causal interpretation.

Now, suppose that we want to estimate models which (among other things) assert that there is no effect of C on D. There are two ways to do this:

1. Set to zero all parameters which pertain to both C and D (equivalently, do not fit any marginal tables which include both C and D as variables) for any models fitted to the ABCD table.
2. Collapse over variable C to create an ABD table; then estimate models for this new table.

These two methods are equivalent in two senses. First, the estimated effects of A and B on D will be the same for both methods. Second, tests of hypotheses about the effects of A and B on D will give identical results for both methods. In other words, any conclusions we draw about the parameters in group (a) are identical under either procedure. This will not be true of the parameters in group (b) but, as I have already indicated, these do not generally have any substantive interpretation.

To illustrate these points, let us return to the data in Table 1. In Table 5, I present the goodness-of-fit statistics for four models fitted to the ABCD table and for four models fitted to the ABD table. All of these models can be interpreted as logit models for variable D as the dependent variable. (For that to be true, it was necessary to fit the marginal table for the independent variables in each model.) Models 1–4 correspond to models 5–8, respectively, in their assertions about the effects of variables A and B on variable D. This is not immediately apparent since the chi-squares (and their associated degrees of freedom) for models 1–4 are substantially higher than those for models 5–8. Yet, the differences in chi-square (and degrees of freedom) among models 1, 2, 3, and 4 are identical to the corresponding differences among models 5, 6, 7 and 8. Thus, tests of hypotheses about the effects of A and B on D yield the same results under either procedure.

In the lower panel of Table 5, I present parameter estimates for models 2 and 6. Both models allow for main effects of variables A and B on variable D but exclude any higher-order interactions. I have separated the parameters into group (a) those which pertain to variable D, and group (b) those which do not. The group (a) estimates are clearly the same under both procedures. In group (b), corresponding parameter estimates not only differ under the two procedures, but also, there are many parameters estimated under model 2 that do not appear at all in model 6 (i.e., all the parameters pertaining to the relationships between variable C

	A.B.C2	−.17	−.8		

and variables A and D). As we have repeatedly observed, however, the group (b) parameters are not relevant to the causal model.

We have shown that models 1–4 are equivalent to models 5–8 with respect to estimating and testing the effects of A and B on D. Yet, clearly, there is an advantage to fitting models to the full table rather than to the collapsed table. While model 5 completely ignores the relationship between C and D, model 1 explicitly asserts that C has no effect on D. Hence the goodness-of-fit statistic gives a direct test of that hypothesis. With a chi-square of 143.8, and 8 degrees of freedom, this hypothesis must obviously be rejected. If we had only collapsed the table over variable C—without performing this test—we would have been led to the misleading conclusion that model 6 fits the data very well. It may fit the collapsed table, but the corresponding model does not fit the full table.

The reader may have noticed that what is being asserted here about the equivalence of collapsing over independent variables, and setting effect parameters equal to zero, differs somewhat from the earlier discussion about collapsing over dependent variables. In the earlier section, we set to zero *all* the parameters pertaining to a given variable, and we asserted that the estimates for *all* the remaining parameters would be identical to those obtained from the collapsed table. Here, however, we set to zero only those parameters describing the effect of a given variable on the dependent variable, and we assert that the parameters describing the effects of other variables on the dependent variable are the same as those obtained from the collapsed table. While this is a different claim, the proof is quite similar. The assertion that differences in chi-square are the same for models 1–4 and models 5–8 follows from Goodman's (1971) demonstration that the chi-squares in models 1–4 can be additively decomposed into two parts: (1) a chi-square for testing the hypothesis that D is conditionally independent of C, given A and B; and (2) a chi-square for some hypothesis about the marginal table ABD. The equality of parameter estimates again follows from Bishop et al.'s (1975:47) collapsibility theorem. The proof is the same as that given earlier, except that a more general version of the collapsibility theorem is invoked.[4]

The more limited claim of this section could actually have been used in the preceding section where the aim was to collapse over dependent variables. Thus, to estimate the effects of A and B on C from the ABCD table, we could have set to zero only those parameters pertaining to both D and C instead of excluding *all* the parameters pertaining to D. The result would have been that estimates and tests of the effects of A and B on C would have been the same as those obtained from the ABC table. However, the parameters describing the relationship between A and B would have differed under the two alternative procedures.

It should also be noted that the results obtained in models 3 and 4 of Table 5 are equivalent to results that would be obtained by collapsing over both variables B and C to create a 2 × 2 table for variables A and D. Specifically, the A.D parameter estimated in model 3 is the same as that obtained from the 2 × 2 table; also, the difference in chi-square between models 3 and 4 is the same as that for the test of independence in the 2 × 2 table.

Collapsing Selected Categories

These results also apply to the case in which some, but not all, of the categories of a variable are collapsed into a single category. In Table 1, for example, education (variable C) has three categories: grade school, high school, and college. Suppose we believed that, net of other variables, there was no difference—in attitudes toward jobs for blacks—between those persons with grade-school educations and those with high-school educations. Yet, we still believed that there was a difference in attitudes between those with college educations and those without. One approach would be to collapse the grade-school and high-school categories into a single category and, then, estimate models for this collapsed table. Models 5–8 in Table 6 do just that. In this table, C′ represents the collapsed, two-category version of variable C. Alternatively, one could constrain the grade-school and high-school parameters to be equal in models for the full, uncollapsed table. While this is difficult to do with ECTA, it is easily accomplished with GLIM and certain other programs.[5] In Table 6, models 1–4 impose such constraints on the parameters for the relationship between the independent variables and the dependent variable. (No such constraints were imposed on the parameters describing the relationships among independent variables, since these have no causal interpretation.)

A comparison of models 1–4 with the corresponding models 5–8 shows that these two methods are, again, essentially equivalent. The chi-squares and degrees of freedom for models 1–4 are higher than those for the corresponding models 5–8, but differences in chi-squares and degrees of freedom within the first group are identical to the corresponding differences within the second group. Although not shown here, the estimated effects of A, B, and C′ on variable D are also the same

7. ABC′, AD, BD, C′D	11.8	4
8. ABC′, AD, BD	94.7	5

---

[4] The generalized version of the collapsibility theorem says the following: First, divide the variables into three mutually exclusive groups; if group 1 is independent of group 2 (but not necessarily group 3), we can collapse over group 1 without affecting any of the parameters pertaining to group 2. In this example, group 1 is variable C, group 2 is D, and group 3 includes A and B.

[5] Inquiries about GLIM should be addressed to Numerical Algorithms Group, Ltd.; NAG Central Office; 7 Banbury Road; Oxford OX2 6NN, U.K.

under either method. As in the preceding section, however, there is an important advantage to the method of imposing constraints on models for the full table; it provides an explicit test of the hypothesis that those constraints are true in the population. Thus, the chi-square for model 1 is a test statistic for the hypothesis that there is no difference—in attitudes about jobs for blacks—between those persons with grade-school and those with high-school educations. Clearly, that hypothesis can be rejected. Models 5–8, on the other hand, have nothing at all to say about that hypothesis.

COMMENTS

KEYNESIAN GOVERNMENT INTERVENTION AND INCOME INEQUALITY

(COMMENT ON STACK, ASR, DECEMBER, 1978)*

In a recent paper, Steven Stack advances what he terms a "neo-Keynesian" model of income inequality, which makes the following predictions (Stack, 1978:883):

> [1.] the greater the direct government involvement in the economy (DGI) the less the unemployment and the less the income inequality;
> [2.] the greater the DGI, the greater the economic growth and the less the degree of income inequality; and
> [3.] that government spending will have an effect on income inequality independent of the level of development.

To test the validity of this model, Stack gathers data for 32 countries and regresses a measure of income inequality on three variables: (a) the sum of expenditures of central government, social security, and public enterprises as a percentage of GNP, 1959; (b) GNP per capita, 1965; and (c) GNP per capita growth rates, 1950–65. Because all the coefficient estimates have the predicted sign, and because the overall equation has a $\bar{R}^2$ of .57, Stack concludes that his neo-Keynesian model is generally consistent with the data. Specifically, he argues that the first and third propositions are strongly supported, but he finds that there is much less support for the second prediction concerning the effects of the rate of economic growth.

These conclusions, I believe, are too hasty. Stack's analysis is flawed by a lack of familiarity with basic aspects of the argument at hand and with elementary principles of data collection and analysis. I shall begin by discussing briefly some of the more obvious (and less important) flaws and then will turn to the more critical problems I find within Stack's paper.

Statistical Problems

To begin, Stack's main set of regression estimates is reported in a confusing and inconsistent way. For example, in Table 2, Stack reports that economic growth has a beta coefficient of −.333, with a t-ratio of 0.22 and a significance level of .005; while the level of economic development has a coefficient of −.239, a t-ratio of 2.02, and a significance level of .05. These figures are, of course, mutually inconsistent and one assumes that the first t-ratio is incorrectly reported. But, even if it is, the figures in Table 2 do not support the statement in the text that, unlike the level of economic development, growth has no significant effect on inequality.

Stack's (1978:887) comparison of the performance of his results with those of others is similarly confused over the issue of sample size and degrees of freedom. While it is true that large R^2s occur when the number of variables approaches the number of cases, Stack's assertion that the same pattern holds with corrected R^2s (or $\bar{R}^2$s) is false. I do not want to belabor the obvious, but the correction to R^2 is introduced *precisely* to compensate for the loss of degrees of freedom that occurs with increases in the ratio of parameters to cases. Stack's (1978:887) rule of thumb that one should have no more than "one variable for every ten cases" underscores his confusion, since the number of degrees of freedom is *not* a simple linear function of the number of parameters in the model and the number of cases analyzed.

One other minor point is worth noting here. The statement, ". . . that the original association between growth and inequality is spurious and that *growth affects inequality indirectly through its association with DGI*" (Stack, 1978:886, italics added), is a non sequitur and reflects ignorance about what a spurious association really is. If the original association is spurious, then the second (italicized) part of his statement is false. This is quite clear from Stack's own Figure 1, which specifies DGI → Growth → Inequality. Obviously, if the association between growth and inequality is spurious, then growth does not *affect* inequality directly or indirectly.

However, even if Stack were to correct these problems, his analysis would remain critically flawed. In particular, there are serious problems with his selection of cases and use of data sources. I shall deal with these, in turn.

Selection of Cases: Keynesianism in East Europe?

Stack places great emphasis on the idea that his is a test of a neo-Keynesian argument. As most readers will be aware, Keynes's argument concerns, inter alia, the effects of government spending and manipulation of the money supply *within the context of capitalist or market economies* (see, e.g., Klein, 1947; the essays in Lekachman, 1964; and Stein, 1969:156–65). In particular, if it is possible not to overstate the obvious, the Keynesian perspective addresses government intervention in market economies, as opposed to the central planning that is typical of the Soviet and East European economies. The distinction here—between Keynesian economic manipulation and central planning—involves fundamental, qualitative differences in both the nature *and* form of government intervention, so that the planners of East Europe and of the Soviet Union are not simply Keynesians writ large. Indeed, the distinction is also implicit in Stack's (1978:882–3) rendering of the argument. For example, after contrasting the United States and Sweden, he writes that

> the impact of government spending on unemployment and income inequality should be felt not only through direct job creation programs in government, but also through the *multiplier effect* or the multiple reinvestment of money obtained from higher levels of consumption in job creative ventures in the private sector. (Stack, 1978:883, italics in original)

Reasonable people would, therefore, expect the analysis to focus on Western and (perhaps) on some Third World countries.

This impression is not contradicted elsewhere in the text of Stack's (1978:884) paper, where we are told, "The present study utilizes Paukert's [1973] data bank," a data series that refers to Western and Third World countries. Only by reading footnote 9 does one become aware of the fact that eight socialist countries are also included in the analysis. Indeed, apart from the list of countries reported in the Appendix, this footnote is the only place in which Stack alludes to the presence of these socialist countries in his study.

An obvious question that this raises is how Stack's neo-Keynesian model performs if we focus on the kinds of economies that concern Keynesians?—i.e., if we exclude from consideration the eight socialist countries? Clearly, the empirical validity of Stack's hypotheses should not depend on the inclusion of centrally planned economies in the analysis.

To pursue this question, I have reestimated Stack's model for those Western and Third World countries that are covered by Paukert (1973:114–5) and for which data on the independent variables are available. The data are taken from the sources used by Stack. Thus, the measure of direct government intervention (DGI) is the sum of expenditures of central government, social security, and public enterprises as a fraction of GNP, and comes from Russett, et al. (1964:65–6). Similarly, figures for both GNP per capita (GNP/cap) and GNP growth rates (EG) are from Taylor and Hudson (1972:314–21). There are 24 Western and Third World countries for which data on income inequality and these three independent variables are available (all 24 of these countries are included in Stack's analysis).

Table 1 reports four sets of estimates. The first row contains metric parameter estimates for all three independent variables for all 24 countries. Of this set of estimates, only that for GNP/cap is more than twice its standard error (t = 2.31), while that for DGI is *smaller* than its standard error (t = .60) and is of the *wrong sign* (remember that, according to Stack, DGI is

Table 1. Regressions of Gini Index of Income Inequality on Government Spending, GNP Per Capita, and GNP Growth Rates**

*** Excluding Italy and Burma, for reasons given in the text.

supposed to *reduce* inequality). However, since there is a positive correlation between EG and DGI (r = .476), it is possible that the effects of DGI are being masked in some way by the inclusion of EG in the model (besides, the estimate for EG is barely larger than its standard error). To check this, the second set of estimates in Table 1 examines only the effects of DGI and GNP/cap. This modified set of estimates produces the same result: the coefficient for DGI remains statistically insignificant and of the wrong sign. In short, both of these sets of estimates provide little support for Stack's neo-Keynesian argument.

There is a problem, however, with these estimates. Two of the 24 countries have strange income inequality data. According to Paukert (1973:125), the figure for Burma constitutes a particularly rough approximation and is therefore of "rather doubtful value."[1] In addition, the Italian figure refers to 1948, a date that precedes that of the independent variables by a huge margin. To ensure that the inclusion of these countries is not affecting the analysis, the third and fourth rows of Table 1 report estimates corresponding to those in the first half of the table for the remaining 22 countries. These revised estimates suggest that the inclusion of Burma and Italy serves only to introduce noise into the analysis. Excluding Burma and Italy raises the $\bar{R}^2$s and increases the F-ratios to levels where they are significant at the .05 level. But the estimated effects of DGI in the third and fourth rows of Table 1 remain statistically insignificant and of the wrong sign.

Another possible objection to the foregoing analysis is that my use of Gini ratios is potentially misleading, because these ratios are insensitive to cases where the Lorenz curves intersect (see, e.g., Atkinson, 1975:29–49; Sawyer, 1976), while they are more sensitive to differences around the middle of the income distribution than they are to differences around the tails of the distribution (see, e.g., Champerowne, 1974). These considerations suggest that we might profitably examine more detailed data on the share of income received by successive population quintiles, ranging from the most- to the least-wealthy. Accordingly, Table 2 reports the estimates for four separate regressions on the three independent variables for the 22 countries analyzed in the bottom two rows of Table 1. The dependent variable in the first equation is the share of income received by the most-wealthy 20% of the population, while that in the fourth equation is the share received by the poorest 40%. Three of the four equations in Table 2 have F-ratios that are significant beyond the .05 level, while the equation for the share of income received by the poorest 40% in the bottom row does not meet this condition. In addition, the first three sets of estimates have higher $\bar{R}^2$s than did the corresponding estimates using Gini ratios. Apart from this, however, these figures simply reinforce the conclusions drawn earlier.[2] In no case is an estimate for DGI in Table 2 more than twice its standard error and, again, in three of the four cases, the estimate for DGI is of the wrong sign.

Table 2. Detailed Regressions of Income Inequality on Government Spending, GNP Per Capita, and GNP Growth Rates (N = 22)**

Dependent Variable	Constant	DGI	GNP/cap	EG	R^2	$\bar{R}^2$	F

---

[1] I should point out that others besides Stack seem to have ignored this caveat of Paukert's. Along with Burma, Paukert (1973:125) lists six other countries for which he judges the inequality data to be of "doubtful value." As far as one can gather (since he provides no list of countries), Chase-Dunn (1975) used all seven of these observations, which constitute almost a quarter of his sample. Similarly, Rubinson (1976) used six of these seven cases.

[2] Note, again, that the same pattern is obtained when GNP growth rates (EG) are excluded from the model (as was done in the bottom row of Table 1).

To summarize, an analysis based on data restricted to market economies provides no support for the neo-Keynesian model advanced by Stack. In particular, DGI has no measurable effect on inequality in market economies. The results Stack reported must therefore be a function solely of the inclusion of eight socialist countries in his analysis which, in turn, means that the results he obtained do not bear on Keynesian arguments.

Data Sources

If Stack's selection of cases fits poorly with his argument, his use of data sources is positively cavalier. Consider his description of the source of his information on government spending. We are told, "Comparative data on government spending were collected as part of the cross-national data archive of Russett et al. (1964)." After a brief discussion of this variable, Stack (1978:885) then states, "Data were available on this measure for 32 countries for which income inequality data are also available." Reasonable people might infer from this description that the data are, in fact, available in the source cited. Unfortunately, any such inference is false. The Russett handbook does *not* include data on government spending for the eight socialist nations that constitute one fourth of the cases analyzed by Stack. Indeed, it does not contain such data for *any* socialist societies.

To understand why data for these countries are excluded from Russett's handbook, it is necessary only to go back to the principal original sources used by Russett and his colleagues, which are the various *Statistical Yearbooks* and the more detailed *Yearbooks of National Accounts Statistics* published by the United Nations. For most of the eight countries, no data are available for *circa* 1959, while those data that are available are simply not comparable to the data available for market economy countries. First, the Russett et al. (1964:65–6) figures refer to *central* government spending; those in the U.N. Yearbooks for socialist countries refer to *general* government spending, which includes local and provincial government spending (Yugoslavia is the only partial exception to this). This in itself makes the data for socialist countries not comparable to the data for other countries. Second, socialist countries do not report their national accounts according to the standard U.N. format that is used by other countries. As a result, the country tables for these societies in the *Yearbooks of National Account Statistics* are all prefaced with the following note (or a close variant of it):

> The concept governing the official estimates of [country name—USSR, etc.] is that of net material product which is defined as the total net value of goods and "productive" services, including turnover taxes, produced by the economy in the course of a year. Specifically, the estimates cover the following economic activities: agriculture and forestry, mining, manufacturing, construction, transport and communication, trade and catering. Economic activities not contributing directly to material production, such as public administration and defence, personal and professional services, and similar activities, are not included.
>
> *For these and other reasons relating to the treatment of particular items, the estimates in the table below are not comparable in concept and coverage with those of the United Nations system of national accounts.* (emphasis added)

These two problems obviously affect the numerator of the term used to measure government influence in the economy (central government expenditures, etc.). Note that the second problem also affects the denominator of the term, GNP. Since the figures on government spending are reported in national currencies, they have to be deflated by GNP expressed in national currency. However, the U.N. *Statistical Yearbooks* report the wealth of socialist countries in terms of net material product, not GNP, and, as I have just pointed out, the two are not comparable. While it is possible to compare the figures on net material product *within* the group of socialist countries, comparing these countries with others is much more difficult (see also the discussion on this point in Russett et al. [1964:150], and Taylor and Hudson [1972:289]).

If data on DGI for the socialist countries are inherently not comparable with those for other countries and, if they are not readily available for all eight socialist economies, how did Stack score these countries on this variable? It appears (Stack: personal communication) that he proceeded by assuming that DGI scores for the "command socialist countries were at the 99 percent level," while those for the "market socialist countries" (presumably Yugoslavia) were "in the 90 percent range" (compare this with the highest score for a Western country [France] of 40% [Russett et al., 1964:65]). In other words, the eight socialist countries were simply assumed to have extremely high DGI scores. While this may help account for the differences between Stack's results and those reported above, the assumption itself is patently unreasonable. Consider the Soviet Union, presumably a "command socialist economy." Recent evidence indicates that even the legal component of the "second" or market economy accounted for at least 22% of GNP in 1950 and at least 10% by 1968 (which suggests that for 1960 a figure of 15% is probably close). Also, even by 1968, estimates suggest that the legal second economy accounted for between 15–25% of household consumption (Grossman, 1977:35). Adding to this the illegal second economy (of unknown size) suggests clearly that Stack's guessed value of DGI for the Soviet Union is far too high (see Grossman, 1977; Katsenelinboigen, 1977). Nor is the second economy an issue only in the Soviet Union—evidence suggests that its legal component is considerably larger in other East European countries (Grossman, 1977:40). These considerations imply that Stack's procedure does not even produce reasonable guesses of the values of DGI for the socialist countries.

In short, Stack fails to identify the sources of his information on government intervention in the socialist economies, and is less than candid about the facts that this information is not available in a form that allows meaningful analysis and that his estimates are simple guesses. Even if the inclusion of socialist countries could be justified on theoretical grounds (and that would be a tall order), these problems with Stack's measure of DGI are crippling.

Similar problems exist with Stack's data on income inequality for the socialist countries. His complete statement on this issue is as follows: "In addition to the data in the Paukert data bank we were able to obtain comparable data on eight socialist nations from the meticulous work of Michal (1973), Szafnicki, (1971), the United Nations (1967), and Yanowitch (1969)" (Stack, 1978:884, fn. 9). Note, first, that—although different sources sometimes give different figures for the same country—Stack does not identify which country values come from which source, or the specific tables or pages that he used in these sources; and, second, that no serious effort is made to justify the comparability of these additional data. More distressing, perhaps, are the facts that a careful reading of these four sources does not satisfactorily resolve the first issue, and that such a reading undermines any claim that the data are comparable with each other, let alone with Paukert's data. Let me elaborate.

In none of the four sources can I find any information for Romania on the size distribution of income among individuals or families. Michal (1973:410–1) gives data for Czechoslovakia, Hungary, and Yugoslavia; Szafnicki (1971:39) has information on Poland; Yanowitch (1969:145–6) discusses the USSR; while the United Nations (1967:Tables 9.19 and 9.20) gives figures for East Germany, as well as data for Czechoslovakia, Hungary, and Poland that conflict with those given in the first two sources, along with partial data for Bulgaria (Table 8.20).

The figures that Michal gives are for the pre-tax size distribution of earners' income, not household or family income (cf., Paukert's [1973:113] emphasis on the latter). The consequences of this distinction are not trivial, as Kuznets (1963:3–8), Sawyer (1976:4–6), and others have stressed.[3] In addition, Michal's data for Hungary apply *only* to "state sector" employees, a group that by his own estimate constituted approximately 60% of the work force in 1960. This means that Michal's information for Hungary is not in a form that can be compared either to his data for the other two countries he considers or to Paukert's figures.

Similar problems arise when we examine Szafnicki's (1971) paper, which examines data from a 1967 sample survey carried out in the city of Lodz, *not* in Poland as a whole. While the specific biases that this introduces cannot be specified precisely, it is clear that Lodz is not representative of Poland. For one thing, it does not reflect rural and agricultural sectors, despite the fact that, in 1960, 47% of the Polish work force was engaged in agriculture (United Nations, 1967:Table 8.28). Another reason for doubting that Lodz accurately reflects Polish society comes from evidence indicating that, of eight socialist countries in East Europe in 1968, Poland had the second highest scores for interregional inequality in industrial employment (Koropeckyj, 1972:73. Poland scored second only to Hungary in this respect).

These considerations undermine Stack's assertion that the income inequality data for socialist countries are "comparable" (this lack of comparability doubtless accounts for Paukert's [1973] decision not to include data on these countries from the United Nations and the Yanowitch studies, even though he used the former study as a source of data on several western European countries). In addition, it is important to note that the sources cited by

---

[3] To be fair, while Paukert claims that the income units for his data are "families or households," this is not always the case. For example, for seven West European countries, his data are from United Nations (1967:Table 6.10), which used taxpayers' income, not family income, as the unit. To gain some sense of the impact of this distinction compare the data that Sawyer reports in his Table 3 with his data for Denmark and Finland (1976:23–4). This and related problems that Sawyer discusses imply that Stack's acceptance of even Paukert's data is insufficiently critical, although Stack is certainly not alone in this respect (cf., Chase-Dunn, 1975; Rubinson, 1976; Hewitt, 1977; and Rubinson and Quinlan, 1977).

Stack provide conflicting data. For example, Michal (1973:410–1) gives a Gini ratio of .226 for Hungary, while the United Nations (1967: Table 9.20) gives .27. Similarly, Szafnicki (1971:39) gives a Gini ratio for "total family income" in Lodz of .166, which is about half the United Nations estimate for Poland as a whole of .29. (I should emphasize that the differences between these conflicting estimates are not trivial. To place them in context, note that for the 22 Western and Third World countries examined in Table 2 above, Paukert's Gini index ranges from .30 to .61, with a mean of .43 and a standard deviation of .09.) One assumes that Stack took the lower figure where possible (since there would otherwise be no point in citing Szafnicki), so that socialist countries are scored as being much more egalitarian than others. Indeed, this helps account for the correlations reported by Stack. While DGI is not related to income inequality when the socialist countries are excluded, a large correlation is readily induced when those countries are included and assigned extraordinarily high DGI scores coupled with very low Gini ratios. A careful examination of the relevant scatterplots and residuals might have revealed to Stack just how artificial this correlation is.

Summary

Stack's claim that his analysis provides support for a neo-Keynesian model of income inequality is groundless. The most critical flaw in his paper is his inclusion of socialist countries, partly because comparable and meaningful data for these countries are not available for the relevant variables, and, partly, because his model falls flat when these countries are excluded from consideration. Most important, however, Keynesian arguments do not apply to socialist economies, because the form of government intervention in these economies is qualitatively distinct from the intervention found in other economies. For this reason, Stack's analysis is irrelevant to the hypotheses that motivated his inquiry.

THE CASE OF THE *MISSING-VALUES* CARD, AND OTHER MYSTERIES: ANOTHER LOOK AT THE EFFECT OF GOVERNMENT SPENDING ON INCOME INEQUALITY

(COMMENT ON STACK, ASR, DECEMBER, 1978)*

The *ASR* recently has published a number of cross-national studies of income inequality (Jackman, 1974; Rubinson, 1976; Rubinson and Quinlan, 1977; Hewitt, 1977; Stack, 1978a; 1978b). This paper reanalyzes the data from one of these studies (Stack, 1978b) and shows that his conclusions are wrong because his analysis is fundamentally flawed; in fact, his conclusions stem from a series of errors. In the process, we touch base with some issues which macrolevel cross-national studies, in general—and cross-national studies of inequality, in particular—cannot afford to overlook.

The Missing Missing-Values *Card*

Cross-national variations in income inequality have been explained in terms of national differences in (1) economic development/industrialization (Kerr et al., 1964; Lenski, 1966; Cutright, 1967; Jackman, 1974); (2) political democracy/socialism (Lenski, 1966; Cutright, 1967; Hewitt, 1977; Stack, 1978a); and (3) position in the world economy (Rubinson, 1976; Bornschier et al., 1978). Stack (1978b) proposes a fourth contender, which he calls *Keynesian* (or, in some places, *neo-Keynesian).* His Keynesian approach asserts that the "degree of direct government involvement in the economy should reduce income inequality through such means as full employment and the facilitation of economic growth" (Stack, 1978b, abstract). For a cross-section of 32 nations Stack finds that government involvement has a significant negative effect on income inequality, with economic level and rate of economic growth controlled; he views this result as consistent with his hypothesis.

I retraced his study, from first datum to last beta coefficient, and found that his results are seriously in error. Let us begin at the beginning. Stack's "Keynesian model" has four variables: income inequality (dependent variable), government involvement (key independent variable), and economic level and rate of growth (control variables). Estimates of per capita GNP and rate of growth of per capita GNP (his measures of economic level and rate of economic growth, respectively) are readily available for almost all nations. Estimates of income inequality (measured by the Gini index) and direct government involvement (measured by level of government spending) are available for only a few countries. Hence, Stack chose as his sample those nations for which he could find estimates of both income inequality *and* government spending. Or, at least, I so interpret his discussion on p. 885:

> Comparative data on government spending were collected as part of the cross-national data archive of Russett et al. (1964). We will utilize their data on the sum of the expenditures of the central government, social security, and public enterprises as a percent of the GNP. . . . Data were available on this measure for 32 nations for which income inequality data were also available. Our study is based on these countries.

In point of fact, however, only 24 of Stack's 32 nations (see his Appendix [Stack, 1978b], which lists the 32 nations) are included in the estimates of government spending found in Russett et al. (1964: Table 17); the eight socialist nations in Stack's sample (Eastern European nations, and the USSR) have no accessible data on government spending.

My first hunch was that Stack found estimates on government spending in sources which he forgot to mention in the article. However, in consulting other data sources, I was not able to locate estimates of government

Discussion with Michael Hughes, Anthony Oberschall, and Gregory Sampson were helpful in the development of this paper. The paper was written and accepted for publication in the spring of 1979; since then other cross-national studies of income inequality have been published. However, the more recent studies do not affect this critique.

Table 1. Zero-Order Correlation Coefficients for Stack's Model, I

Variable	Inequality	Government Involvement	Economic growth
Government Involvement	−.74[a], −.16[b]		
Economic growth	−.46, −.48	.61, .48	
Economic level	−.24, −.23	.01, .39	−.06, −.04

[a] Coefficient reported by Stack (1978b:Table 1).
[b] Coefficient I obtained using Stack's measures and data sources.

spending for any of the socialist nations except Yugoslavia (and then only for 1970–73; IBRD, 1976:388), even though I was able to locate 48 other nations, missed by Stack, with data on both government spending and income inequality. This led me to guess that the eight socialist nations in Stack's sample are indeed missing data on government spending, his statements to the contrary notwithstanding.

To test my hunch that Stack was not able to locate these data I used his measures, his data sources, and his sample in an attempt to duplicate his correlation matrix (see Appendix, here, for data). Table 1 gives the results. Note that I was successful in duplicating his correlations between inequality and economic growth, inequality and economic level, and economic growth and economic level (I am willing to assume that differences of the order .02 are due to rounding errors or differences in minor judgments that had to be made in data collection). Apparently, then, I was able to duplicate his data on economic growth, economic level, and inequality.

However, the correlations which include government involvement diverge sharply. Of particular interest is the correlation between government involvement and inequality, since Stack's conclusions hinge on this coefficient: in Stack's analysis 55% of the variance in inequality is associated with government involvement (r = −.74), while in my reanalysis only 3% of the variance in inequality is associated with government involvement (r = −.16).

What could cause such a large discrepancy? Assume for the moment that Stack was able to locate data on government involvement for the socialist nations. What level of government spending for these eight cases would we need, to change the correlation from −.16 to −.74? Obviously, it would need to be larger than the mean for the 24 nonsocialist nations, since the level of inequality is lower for the socialist nations (mean = .24 versus .43). Suppose that, in these eight nations, government spending reached 99.9% of the GNP: Would that be large enough to change the correlation from −.16 to −.74? To find out, I gave the socialist nations a value of 99.9% on government involvement and recomputed the correlations. The results are given in Table 2. The assumption that government spending reaches 99.9% of the GNP in socialist nations does indeed duplicate Stack's correlations (within .03 in all cases). Coincidence? I think not. Note that 99.9 is a value one would likely use for missing data. While *we* know that a value of 99.9 for government spending is ridiculous, a computer does not. In short, circumstantial evidence indicates that a missing-values card was missing in Stack's computer program.[1]

Does this mistake affect Stack's conclusions? Table 3 compares Stack's results with the results where the missing data card is

Table 2. Zero-Order Correlation Coefficients for Stack's Model, II

Variable	Inequality	Government Involvement	Economic growth
Government Involvement	−.74[a], −.75[b]		
Economic growth	−.46, −.48	.61, .64	
Economic level	−.24, −.23	.01, .01	−.06, −.04

[a] Coefficient reported by Stack (1978b:Table 1).
[b] Coefficient I obtained using Stack's measures and data sources, giving the eight socialist nations a value of 99.9% for government involvement.

---

[1] The alternative is to assume that, for the socialist nations, Stack *intended* to code government spending at or near 100 percent of the GNP—that is, Stack arrived at his government involvement measure for the socialist nations by equating government spending with GNP. To be sure, in these nations, the bulk of GNP flows from the public sector, but this is clearly not the type of government spending Keynes had in mind; a government spending/GNP ratio which is near 1.0 is hardly Keynesian, since Keynes did not advocate the abolition of the private sector. I will discuss this point further when I focus on Stack's measures; here, it suffices to note that operationalizing Keynesian theory in such a way that it makes Keynes a socialist is no less a mistake than forgetting the missing-values card.

Table 3. Determinants of Inequality, Stack's Model: Stack's Results vs. Corrected Results

Independent Variable	Stack's Results[a]			Corrected Data[b]		
	b[c]	β[d]	F	b[c]	β[d]	F
Government Involvement	−.003	−.72	23.4	.004	.29	1.6
Economic Level	−[e]	−.24	4.1	−.00005	−.37	3.2
Economic Growth	−.002	−.03[f]	.05	−.042	−.64	8.9
R^2 (adjusted)	.57			.25		

[a] From Stack (1978b:Table 2)

[b] Pairwise deletion of missing cases was used. The direction (though not the magnitude) of the effects is the same under listwise deletion: b is .001 for government involvement, −.00005 for economic level, and −.014 for economic growth.

[c] Metric regression coefficient.

[d] Standardized regression coefficient.

[e] Unknown; Stack reports −.000.

[f] Stack reports −.33, but that is apparently a typographical error.

firmly in place.[2] Note that correcting the data (1) reverses the sign of the effect of government involvement and (2) reverses the order of importance of the variables (note the β's and F's). The former is particularly devastating to Stack's paper, since its central message is that government involvement *reduces* inequality. In sum, Stack's finding that government involvement reduces inequality apparently is based entirely on an error in the analysis; when this error is corrected, his data do not support his hypothesis.

Are there other serious mistakes in this analysis? Yes; and they should be detailed, since other macrolevel cross-national studies can be subject to some of these same mistakes. Further, these other lapses, while less stunning than the mishandling of the missing data for the socialist nations, are no less devastating to Stack's conclusions. I have grouped these lapses into three categories: model specification, cross-sectionalism, and operationalization and measurement.

Model Specification

Alternative models. As noted at the outset, Stack's study is a recent addition to an emerging body of literature on cross-national variations in income inequality. Stack cites this literature but, for the most part, he does not build upon it. For example, Rubinson (1976) found that a nation's dependence on external markets, its economic penetration by foreign nations, and its state strength all are significantly related to its degree of income inequality. Stack cites Rubinson's study, but he fails to control for any of these factors. Stranger still, in an earlier study, Stack (1978a) himself concluded that the "most important determinant of the degree of inequality is . . . democratic performance" (p. 271) and, thus, "the internal political model should not be neglected" (p. 272), yet measures of the polity are notable for their absence in his later paper. If political democracy does indeed affect income inequality; then it should be included in models of income inequality; if Stack (1978a) is correct, then Stack (1978b) uses a misspecified model.

What happens to the effect of government involvement when these other variables are controlled? Tables 4 and 5 give the results (for the uncorrected and corrected data, respec-

Table 4. Effect of Direct Government Involvement (DGI) on Inequality, *Uncorrected* Data: Alternative Models

Variables Controlled	Effect of DGI[a]		
	b[b]	*s.e.(b)*[c]	*F*
1. Economic level & economic growth (Stack model)	−.003	.001	23.4
2. Stack model & political democracy	−.002	.002	.9
3. Stack model & political democracy & state strength	−.001	.002	.2
4. Stack model & political democracy & state strength & dependence on foreign markets	.001	.002	.7

[a] Uses Stack's metric on DGI.

[b] Metric regression coefficient.

[c] Standard error of regression coefficient.

---

[2] To avoid redundancy, I do not report my results where I omit the missing-values card; they parallel Stack's results, as one would expect from the similarity in the correlations (Table 2).

Table 5. Effect of Direct Government Involvement (DGI) on Inequality, *Corrected* Data: Alternative Models

Variables Controlled	Effect of DGI[a]		
	b[b]	*s.e.(b)*[c]	*F*
1. Economic level & economic growth (Stack model)	.004	.003	1.6
2. Stack model & political democracy	.001	.003	.2
3. Stack model & political democracy & state strength	.001	.003	.1
4. Stack model & political democracy & state strength & dependence on foreign markets	.0001	.003	.001

For [a], [b], and [c] see notes to Table 4.

tively) for three alternative models. Following Stack's (1978a) advice, I added a measure of political democracy to Stack's (1978b) Keynesian model. Democracy is a difficult construct to operationalize; no measure enjoys universal acceptance. I used a measure readily accessible to me, the "political participation" index of Olsen and Firebaugh (1975); this measure parallels Jackman's (1974) "democratic performance" index on three of its four indicators (for the fourth indicator it replaces his measure of voting turnout with a measure of the freedom for opposition groups to organize). With the addition of this index, government involvement does not even attain statistical significance in the *uncorrected* data (Table 4).

In the second alternative model, I included a measure of state strength as well as of political democracy. Rubinson (1976) used government revenue/GDP as his primary measure of state strength, but Stack (1978a:fn. 1) criticized this measure for being too restricted. In view of this criticism, I replaced government revenue/GDP with an index which combines indicators of legislative effectiveness, administrative modernity, government size, and public order (from Olsen and Firebaugh, 1975). In this model, as in the previous one, the effect of government involvement falls short of statistical significance.

Finally, I added a measure of dependence on external markets. Following Rubinson (1976) and Stack (1978a), I measured this by exports/GDP. Once again the effect of government involvement is small (it is even in the wrong direction) and falls far short of statistical significance. In sum, under these reasonable alternative specifications the large, statistically significant, effect of government involvement reported by Stack disappears.[3]

Causal direction. Consider Stack's causal model (Stack, 1978b, Figure 1): economic level (per capita GNP in 1965) affects income inequality (*circa* 1960) directly, and indirectly through government spending in 1959 and economic growth (rate of change of GNP per capita, 1950–1965); government spending affects inequality directly, and indirectly through economic growth; and economic growth affects inequality directly. We note immediately that some of the effects in this model operate backward in time: 1965 GNP causes 1950–1965 rate of growth of GNP, 1959 government spending, and 1960 income inequality; and 1959 government spending causes 1950–1965 rate of growth of GNP.

Worse, this model ignores some very likely reciprocal effects (see Rubinson and Quinlan, 1977). For example, there is an extensive body of literature in economics about the effect of income distribution on economic growth. Also, it seems likely that inequality could affect government spending (for example, during recessions government spending may increase in response to increases in unemployment and inequality).

Omission of key Keynesian variables. In his abstract, Stack asserts that the paper "tests the Keynesian notion that the degree of direct government involvement in the economy should reduce income inequality through such means as full employment and the facilitation of economic growth." Similar statements appear throughout the paper.[4] When we get to his model, however, we search in vain for a mea-

---

[3] Stack (1978b:fn. 13) criticizes Hewitt for having *too many* variables in his analysis: "Hewitt (1977) violates one statistical rule of thumb by having more than one variable for every ten cases in his sample." But such a rule was never intended to be a justification for misspecification; when the cases/variables ratio is too small, adding cases is much preferable to purging causal variables.

But could Stack have increased his sample size? Yes; Jain (1975) has more complete data on inequality than Stack's source, Paukert (1973), and *World Tables 1976* (IBRD, 1976:44–390) has more complete data on government spending than Russett et al. (1964). Merging these four sources, I counted 72 nations with data on both inequality and government spending. Stack (1978b:fn. 2) rejects the Jain data as unreliable. Yet, for the 27 nations in Stack's analysis which are also in Jain, inequality measures correlate .96. Apparently, if Jain's data are unreliable, then so are the data Stack used.

[4] For example, p. 883:

> In summation, we anticipate that the greater the direct government involvement in the economy

sure of employment. I can appreciate the fact that comparable, reliable employment data are unavailable for most nations; but a paper which claims to test the notion that government spending reduces inequality through its effect on employment should either include a measure of employment or modify its claims.

The omission of employment is a serious lapse. Without the proper intervening variables it is impossible to eliminate alternative explanations for an observed relationship between government spending and inequality. For example, it seems plausible that government spending could reduce inequality, not because that spending is "Keynesian" (that is, promotes employment) but, rather, because that spending is substantially financed by progressive taxation (which by definition reduces inequality).

Stack does include a measure of the other key intervening variable, rate of economic growth. But does economic growth mediate the effect of government spending on inequality? Let us forget for the moment all the flaws in the analysis and take Stack's findings at face value. Note that *in his own analysis* Stack finds that economic growth has no effect on inequality (see Table 3, here). Of the two key intervening variables in the Keynesian model, then, Stack omits one and finds that the other has no effect. Hence, it is hard to share Stack's (1978b:886) view that his "results indicate support for the (Keynesian) model."

In short, aside from the missing data problem, Stack estimates a model (1) which fails to control for demonstrated causal variables and changes dramatically when they are added; (2) which has causal effects working backward in time; (3) which ignores the likely possibility of reciprocal effects; and (4) which does not work for one of the key intervening variables in the theory and omits the other one. These shortcomings suffice for dismissal of Stack's results. This is not to say that the "Keynesian approach" to income inequality is wrong (perhaps with better data and better-executed research one could show that Keynesian policies do, indeed, reduce a nation's income inequality). But it is to say that Stack's demonstration is unconvincing and should be ignored.

Cross-sectionalism

Cross-sectionalism refers to the use of cross-sectional (particularly cross-national) data to make causal inferences (Irwin, 1977). In some cases causal inference from cross-national data is appropriate (Firebaugh, forthcoming). Unfortunately, the cross-national relationship between government spending and inequality does not appear to be such a case. Students of income inequality often are impressed by the stability of inequality over time for a given nation (e.g., Nicholson, 1970, and Rubinson, 1976:646). Income inequality in the U.S., for example, has remained relatively constant throughout this century (Turner and Starnes, 1976: chaps. 2 and 3), in spite of some rather remarkable changes in the U.S. economy during this period. One of these changes was a marked increase in government spending/GNP. Other nations exhibited similar patterns. Time-series data on government spending are available for 23 of the nations in Stack's sample. From 1950 to 1970, the government spending/GNP ratio increased for 13 of these nations, remained the same for two, and decreased for eight (IBRD, 1976:Series I). However, as Stack (1978b:883) notes, disaggregated measures of government spending are more meaningful, since certain types of government spending are more relevant to income inequality than others. Significantly, increases in Social Security spending (Wilensky, 1975: Table 2) and government nondefense consumption spending (IBRD, 1976:433) outstripped increases in GNP in industrial nations from 1950 to 1970, yet there was little if any change in income inequality in these nations during this period.

Lieberson and Hansen (1974) faced a similar antinomy in their study of language diversity and national development (measured by urbanization). In particular they found that language diversity and urbanization are negatively related for a cross-section of 109 nations. For a given nation over time, however, they found no correlation between language diversity and urbanization, since language diversity (like income inequality) is relatively constant in a nation over time. Their conclusion was that the negative cross-national relationship between language diversity and urbanization is spurious.[5] I would be inclined to a similar conclu-

---

(DGI) the less the unemployment and the less the income inequality. Also, the greater the DGI, the greater the economic growth, and the less the degree of income inequality.

[5] Their explanation for the negative cross-national relationship was as follows: a nation's language diversity depends largely on the way that nation was formed. For older nations, language was an important determinant of national boundaries; for newer nations, language has been a less important determinant. Also, economic development is related to age of nation; older nations tend to have a higher economic level. Newer nations, then, tend to be both more heterogeneous in language and less developed economically—hence, the cross-national relation-

sion about negative cross-national relationships between government spending and income inequality. Stack gives us no explanation of why we should believe his cross-sectional results when they are apparently inconsistent with trends over time; indeed, unlike Rubinson (1976), Stack does not even attempt to reconcile his cross-sectional results with the apparent time-series pattern.

Operationalization and Measurement

On the choice of measures and metrics. Different cross-national studies often employ different measures of the same underlying construct. For example, level of economic development has been variously measured by per capita GNP, per capita energy consumption, percent of labor force in the secondary or tertiary sectors, etc. How, then, does one decide which measure to use? Often, the criterion is correlation with the dependent variable; thus, Stack (1978b:884) chose per capita GNP as his measure of economic level because it had the highest correlation with income inequality. This is a poor practice.

First, correlated measurement error can inflate the observed correlations. Hence, where correlated measurement error is present (as in much cross-national research), the measure which correlates highest with the dependent variable is likely that measure whose measurement error correlates highest with the measurement error of the dependent variable. Stated differently, the measure that correlates highest with the dependent variable is likely the worst measure, not the best. Second, choosing on the basis of observed correlations seems to reduce the possibility of falsification: if I want to show a relationship between X and Y, then choosing a measure of X on the basis of its correlation with Y seems to be a handy way to guarantee success.[6]

In cross-national research, one finds not only different measures for the same construct but also the same measure for different constructs. For example, in their cross-national study of the determinants of fertility, Friedlander and Silver (1967:41) use radios per capita as a proxy for frequency of sexual intercourse (on the assumption that listening to the radio is a substitute); others have used radios to measure quite different constructs. Similarly, Stack uses government spending/GNP to measure Keynesian notions of government involvement in the economy; while Rubinson (1976) uses a similar measure, government revenue/GDP, to measure a very different construct, position in the world economy. I suspect that it is this measurement anarchy—the use of different measures for the same construct and the same measure for different constructs—which accounts in large part for the noncumulative nature of much macrolevel cross-national research in sociology.

Even where there is agreement on the measure, there may not be agreement on the metric. The problem in cross-national research is that many measures are actually ordinal, not interval. This raises the question of whether interval scale techniques, such as regression analysis, are appropriate (Kim, 1975, concludes that they are). An important related issue is that of interpreting nonlinearities in the observed relationships. In the absence of an established metric, how does one know whether observed nonlinearities reflect nonlinearities between the measures and their constructs or actual nonlinearities between the constructs? Stated differently, how do we know which nonlinearities are due to the nature of the measures and which have substantive significance?

This is not an idle question; for example, on the basis of his finding that the cross-national relationship between inequality and per capita energy consumption (*circa* 1960) is nonlinear, Jackman (1974) concludes that economic development reduces inequality to a greater extent at early stages of industrialization than at later stages. But how do we know that per capita energy consumption is a linear measure of economic development? In 1960, the gap between Belgium and Switzerland in per capita energy consumption was about the same as the gap between Switzerland and Nepal (Banks, 1971:Segment 8); but can we say that the difference between Belgium and Switzerland in economic development was about the same as that between Switzerland and Nepal? If not, then we may want to use as our measure of economic development some transformation of per capita energy consumption, such as its logarithm; and Jackman finds that the logarithm of per capita energy consumption is *linearly* related to inequality. In sum, substantive interpretations of nonlinear relationships between measures are tenuous unless one can first establish that the measures are linearly related to their underlying constructs.

---

ship between language diversity and economic development is negative, even though the two variables are unrelated over time.

[6] Since GNP, energy consumption, etc., correlate so highly, I doubt that Stack's results were affected by the measure of economic level he used. Nevertheless, I do object to his method of choosing this measure; and I felt that I should mention these objections, since this method is commonly used in cross-national research.

Inequality. Allison (1978:865) observed, "Although inequality has long been a topic of intense interest to sociologists, few have bothered to carefully specify what they mean by the term." To say that we are interested in income inequality begs a number of questions (Lampman, 1973). Are we interested in inequality merely at a given point in time—or inequality in lifetime earnings? (The former overstates the latter: Dich, 1970.) Are we interested in wage inequality or household inequality? (These are quite different; if households have different numbers of wage earners, equality across households implies inequality in wages, and conversely.) Should we adjust for size of household? If so, do we give children and adults equal weighting?

Why are we interested in cross-national variations in income inequality? In itself, inequality in *income* may not be as interesting as many sociologists think. Indeed, I suspect that what cross-national studies of income inequality are really interested in (though they usually do not state it explicitly) is inequality in standard of living, or economic inequality. However, the use of income inequality as a proxy for economic inequality can be questioned, since the relationship between income distribution and standard-of-living distribution varies substantially across nations. First, in some nations, employees (especially the best-paid employees) are paid large fringe benefits which are overlooked not only in the calculation of income tax but also in the calculation of income inequality. Second, income distributions do not take government services into account. Nations vary considerably in the extent to which governments provide or subsidize education, health care, transportation, housing, food, etc. Third, in some nations, purchasing power is determined by factors other than income. In eastern European nations, for example, certain consumer goods are chronically in short supply; waiting lists are made and, typically, political position is more important than income in determining one's position on the list.

In short, the relationship between income inequality and inequality in living standard is complex. It is also largely uncharted in sociology. Typically, we do not even know whether income inequality overstates or understates inequality in living standard; on the basis of the omission of government services from the income inequality measure, we would expect this measure to overstate economic inequality, while on the basis of its omission of salary payment-in-kind we would expect it to understate economic inequality. We can certainly assume that these factors vary across nations. And therein lies the potential danger in using income inequality as a proxy for economic inequality: to the (unknown) extent that income inequality understates (or overstates) economic inequality differently across nations, to that same extent the cross-national correlation between income inequality and economic inequality is attenuated.

Government spending and Keynes. Stack uses government spending/GNP as his "Keynesian" measure—that is, nations with a higher level of government spending/GNP are assumed to be more Keynesian than those with a lower level of government spending. A brief review of Keynesian theory will reveal that this is a misleading oversimplification.

Consider a nation's real GNP (total output), Y. For a given level of technology (T), and stock of fixed land and capital (K), total national output is determined by employment. Hence, for a particular nation at a particular point in time, there exists a unique level of maximum national output, Y_F, which can be achieved only at full employment.

Keynes departed from classical economic theory when he argued that there is nothing inherent in a market economy to guarantee that the actual output (Y) will correspond to the potential—full-employment output (Y_F). If Y is not necessarily Y_F, then what determines Y? Aggregate demand; that is, $Y = C + I + G$—where C is consumption (the total demand for all goods and services by private consumers), I is investment (the total demand for investment goods by private industry), and G is government (the demand for goods and services, both consumption and investment, by the government).[7] With C and I constant, then, an increase in government spending will increase Y. This suggests the Keynesian cure for unemployment and an underachieving economy: increase government spending enough to raise Y to Y_F.

In Keynesian theory, then, the proper level of government spending is that level which raises Y' to Y_F (where Y' is $C + I$). If the gap between Y' and Y_F is large, government spending should be high. If the gap between Y'

---

[7] In an open economy, exports and imports also enter the equation; in this brief exposition, however, there is no need to add this complication.

Some readers may wonder why, in detailing the weaknesses of Stack's operationalization of Keynesian theory, I have not pointed out that, for Keynes, government manipulation of the money supply is at least as important as government spending. This is a problem with Stack's analysis, to be sure, but it is a problem which he recognizes (Stack, 1978b:fn. 5); I have tried to limit this comment to major problems which Stack fails to mention.

and Y_F is small, however, Keynesian theory advises *against* high government spending; high government spending would be inflationary (McConnell, 1966:257–8). Government spending/GNP would be a suitable operationalization of Keynesian policies, then, only if we could assume that (Y_F-Y')/GNP is similar for all the nations in the sample. Clearly, such an assumption is false; the labor situation varies markedly from nation to nation in Stack's sample (compare, for example, India and West Germany). Hence we cannot equate Keynesian theory with high government spending, as Stack does in his operationalization of the theory.

Note, also, that Keynesian theory views government spending as a *supplement* to private consumption (C) and investment (I). The purpose of government spending is *not* to replace C + I but, rather, to raise C + I + G to the potential output, Y_F. Stack (pp. 882–3) seems to appreciate many of these points in his discussion of Keynesian theory. Surely, then, he did not *intend* to code his Keynesian measure, government spending (G)/GNP (G + I + C), as 1.0 (or nearly 1.0) for the socialist nations. Since government spending/GNP in 1959 was .39 for the United Kingdom and Sweden, and .21 for the U.S. (see Appendix, here), such a coding would imply that the socialist nations are 2½ times as Keynesian as the United Kingdom and Sweden and 5 times as Keynesian as the U.S. Surely, this is false; indeed, it seems wrong to call the socialist nations Keynesian, at all. The abolition of the private sector is not Keynesian; it is socialism.

Conclusion

No matter how you view them, Stack's results are wrong. His results depend entirely upon his coding government spending/GNP as 1.0 (or thereabouts) for the eight socialist countries in his sample. There are two interpretations for this coding. One is the assumption that it was accidental; the missing-values card was missing. The other explanation is that Stack intended this coding, thereby distorting Keynesian theory beyond recognition by implying that Keynes advocated the abolition of the private sector. Further, *even if we ignore this problem and take his data at face value,* his results do not hold under more complete model specifications. In particular, controlling for political democracy—a variable which Stack (1978a) himself insists should be controlled for—eliminated the effect of government spending on inequality. Finally, *even if we take his empirical findings as correct*—that is, even if we take his data at face value *and* assume that his model properly represents Keynesian theory—*then his conclusion is wrong;* Keynesian theory is not supported, since (1) his results show that economic growth does *not* mediate the effect of government spending on inequality and (2) he gives no evidence to eliminate the alternative hypothesis that government spending reduces inequality because it is related to redistributive taxation and not because it is related to employment.

Quantitative cross-national research is not easy; it must be carefully conceived and carefully executed. Unlike another critic of cross-national studies of income inequality (Bach, 1977), however, I do not hold that quantitative cross-national research is merely an exercise in futility. I have faith that quantitative cross-national research on inequality, properly done, can advance our understanding of this important subject.

DIRECT GOVERNMENT INVOLVEMENT IN THE ECONOMY: THEORETICAL AND EMPIRICAL EXTENSIONS

REPLY TO JACKMAN AND FIREBAUGH*

Jackman's main criticisms are (1) a Keynesian model of DGI is inappropriate for the socialist nations; (2) the estimates of DGI for the socialist nations are too high; (3) the income inequality data for the socialist nations underestimate their inequality levels and are not comparable to those of the capitalist nations; (4) if we restrict the sample to the capitalist nations, the model no longer fits the data.

Firebaugh reiterates many of Jackman's criticisms and adds several important ones, including the notion that the model is misspecified. These criticisms, on the surface, may seem to have serious and negative consequences for the DGI model. However, these criticisms tend to be premature and are sometimes marked by errors and fabrications. First, for example, while a strictly *Keynesian* model of DGI may be inappropriate for socialist nations, the umbrella of the general DGI argument certainly covers the socialist case.[1] Second, if we use lower, alternative estimates of DGI, we obtain the same results. Third, if we use the most comparable income inequality data, which maximize the degree of estimated socialist inequality, we still find that the model is correct. Fourth, if we draw a larger, more representative sample of capitalist nations, the DGI is again supported by the analysis. Finally, Firebaugh's criticisms have a number of problems associated with them—such as his alternative specifications, all of which include a measure of political participation that introduces a severe bias against nonwestern systems making the analysis meaningless.

This reply suggests that the comments of the critics are largely inconsequential to the basic validity of the DGI model.

SOCIALIST DGI THEORY

Jackman's long argument that Keynesianism is nonapplicable to eastern Europe is largely irrelevant to the *general* DGI model, as is Firebaugh's statement that it seems wrong to call the Communist bloc nations Keynesian at all. Both make the mistake of limiting DGI theory to Keynesianism. DGI mechanisms can include much more than simple government spending, especially in the case of command socialism. While my original article stressed Keynesian DGI mechanisms, it does not take much imagination to extend the argument to DGI mechanisms in socialism. For example, there is a sound consensus (in the field of comparative economics) that DGI is substantially higher in socialist nations (Leeman, 1977; Holesovsky, 1977). The market is brought under human control through the nationalization of the means of production and the centralization of economic power. This centralized command over economic resources increases the probability of solving the basic "Keynesian" problem of disequilibrium between savings, consumption, and investment. Consequences of such an economic equilibrium relevant to the study of income inequality include full employment and high economic growth rates.

---

* Direct all communications to: Steven Stack; Department of Sociology; Indiana University; Indianapolis, Indiana 46202.

[1] This point was made, although briefly, in footnote 9 of my original paper (Stack, 1978a). In addition, however, the notion that Keynesian analysis is irrelevant to socialist systems is an exaggeration. Jackman ignores the substantial relevant literature on the convergence thesis. The literature on this concept has included works by such western authors as Tinbergen, Galbraith, and Wiles—as well as by such socialist thinkers as Bregel, Dalin, and Vajda (Millar, 1972). To the extent that the systems are converging, we would anticipate that socialist backsliding towards market mechanisms might have some relevance for Keynesian economics.

I would like to take this opportunity to correct two errors in my original article. On page 880, line 7, this phrase should be inserted: political development theory (Lenski, 1966; Cutright, 1967; Peters, 1973; Hewitt, 1977; Rubinson and Quinlan, 1977). Also, in Table 2, under computed value of Student's t, the two asterisks next to the value −.221 for the variable EG should be removed.

First, there is the notion that, under conditions of centralized planning, unemployment should be low or nonexistent. In contrast to capitalism—where there is often an imbalance between savings and investment, since the relevant decisions are made by many private individuals—there is coordination of such decisions in socialism. Since investment is financed from state revenue, and since the level and distribution of investment is state-determined, there is an identity of savings decisions and investment decisions, not a separation of them (Dobb, 1960; Nuti, 1978).[2] In addition, consumption levels also are manipulated from the same command centers. As Bornstein (1978) points out, the level of aggregate demand is normally kept high through ambitious national planning. One consequence of this coordination of the Keynesian categories of savings, investment, and consumption is full employment. While there are fluctuations in economic activity resulting primarily from changes in growth rates of investment and output, these are handled in such a way as to preclude periodic recessions in which workers are laid off (Bajt, 1971). On the microlevel, when a worker is no longer needed because of such considerations as automation, the management is typically expected—or even legally obligated—to reassign him/her, with retraining if necessary, to another department, or to another firm in the same area (Bornstein, 1978). The low rate of unemployment in the command socialist nations, then, is one way in which socialist DGI is responsible for less income inequality.

Socialism eliminates one of the causes of low wages found in capitalism. In the literature on the causes of poverty and the dual economy (Wachtel, 1974), it is often argued that capitalism has no way of effectively transferring part of the high incomes of the advanced technological sector (e.g., heavy industry) of the economy to augment the low incomes being made in the nontechnological sector (e.g., services). Capitalism maintains inequality by its inability to disrupt the dual economy of high-paid workers in the technological sector and low-paid workers in the nontechnological sector. In contrast, in command socialism, given the centralization of economic authority, the gains from productivity in the technological sector can be redistributed. They are often used to promote the general wage level of all workers in the society, as well as to reduce prices and to expand the social consumption fund (Wilczynski, 1977:112). This redistribution lessens inequality.

There are additional links between socialist DGI mechanisms and reduced income stratification. As Parkin (1971) points out, wage differentials are set by national wages boards. This is in contrast to capitalism wherein many individual enterprises set incomes in accordance with a variety of forces. The centralized authority of the state replaces, to an extent, the supply and demand mechanism of the market in capitalism. Given the egalitarian nature of socialist wages ideology, this centralized power tends to be used to decrease wage differentials, in the long run. For example, in the Soviet Union in recent years, the ratio of the average income of the highest-skilled workers to lowest-skilled workers has decreased from 3.68 to 3.2 in ferrous metals, from 2.7 to 2.0 in the petroleum industry, and from 2.71 to 2.0 in the machine construction sector (Kirsch, 1972). Other national wage policies designed to reduce inequality include increasing the minimum wage faster than the mean wage level. For example, in East Germany between 1971–1973, the minimum monthly wage increased from 325 to 392 marks (or by 20.6%) while the average wage increased by only 10.6% (Bruckner, 1974). The most detailed study of such wage policies concluded that

---

[2] Liberal economic theory takes issue with this sharp distinction (Galbraith, 1967). To the extent that corporations finance their investments internally, and not through the big banks, Dobb's distinction is overdrawn. Galbraith's notion of the growing independence of the corporation from finance capital would support the convergence thesis of economic systems (Tinbergen, 1961. However, there is still imperfect coordination of savings and investment in the "new industrial state," in the sense of the lack of coordination of investment ventures *among* individual corporations.

Yanowitch (1969) may be correct when he spoke of socialist "income revolutions" (Kirsch, 1972:184).

Through eliminating private property, socialism largely abolishes the sources of several types of income that are received by a privileged few in capitalism: capital gains, dividends, and rent. Taking the eight socialist nations in this study as a whole, 92% of the farming land is in the socialist sector, and 95% of all national income is contributed by this sector (Wilczynski, 1977:22).[3] The nationalization of the means of production reduces inequality through eliminating incomes from property ownership.[4]

MEASURING SOCIALIST DGI

Jackman has several criticisms of the socialist DGI measures. He states that they are "guesses," that they are probably too high, and that (this, he implies) alternative data might yield different results. Firebaugh states that such high values are "surely false." Firebaugh attributes this "mistake" to the possibility that I left out a missing-values card in my SPSS program. This, incidentally, would have been hard for me to do since I did not even use SPSS. I used COSAP, instead. The small computer I had at my disposal would not handle SPSS. COSAP does not have a procedure for handling missing values.

Data from the United Nations (1978) were incorporated into the estimation procedure for the socialist nations. For example, for Czechoslovakia, only 1,873 million koruny of primary income came from the private sector out of 172,304 million koruny of net material product. To this amount one can add 6,138 million koruny from the personal agricultural plots of households. Private sector income totaled less than 4% of net material product. A DGI figure in the high nineties does not seem "crippling" (as Jackman states) or "ridiculous" (as Firebaugh contends). For Hungary, the total private sector income amounted to less than 2% of total net material product.

Jackman's central basis for criticizing my DGI figures (Firebaugh provides no hard evidence) are some estimates of DGI taken from a CIA study cited by Grossman (1977). These CIA data place the Soviet DGI level at 90%. Jackman implies that there is evidence of it being even higher in other eastern European nations. Grossman (1977:40), however, states only that the "scope" (types of private activities allowed) of private activity is probably wider in other socialist nations. In addition, Grossman gives no evidence supporting this remark.

Other sources of data tend to support my estimates rather than those of the CIA and Grossman. For example, Wilczynski (1977:68) gives the following estimates of socialist DGI: USSR, 96; Hungary, 97; Czechoslovakia, 95; Romania, 95; Yugoslavia, 76; and East Germany, 94. Do these alternative data yield different results? Table 1 gives the results of the regression analysis using Wilczynski's estimates of socialist DGI. The results are largely the same. DGI is still the most important determinant of inequality. GNP/Capita still exerts a significant effect. Economic growth still does not. The amount of variance explained by the model drops by only a few percentage points.

The results shown in Table 1 should be taken with some caution, as Jackman correctly points out that there are differences between socialist and capitalist techniques of national income accounting. Indeed, estimates of socialist GNP are usually 10 to 20% *less* than what they would be if using western methods of calculation. One way of checking the results of Table 1 is to collapse DGI to a dummy variable, wherein capitalist nations receive a score of zero and socialist nations receive a score of one. This categorization seems to be in order, since literally all scholars of comparative economics agree that there is far more DGI in socialist nations than in capitalist nations. The results of this regression are given in Table 2. Measuring DGI in this fashion does not change the basic results of my original article, either. Again, the results are almost exactly the same. In addition, even more of the variance is

---

[3] Jackman exaggerates the importance of the private sector in socialism. Most activity in the private sector is petty bourgeois, in form, wherein a person operates a small enterprise, such as handicrafts, as an owner-worker, and has no employees. However, the private hiring of labor, while exceptional, does exist. In Poland, for example, there is a total of 200,000 persons (or 2% of the labor force) working as employees in the private sector. However, this activity is carefully regulated and held in check through DGI by such mechanisms as heavy taxation and such rules as the requirement of employers to work alongside their employees (Wilczynski, 1977:99).

[4] Additional reasons as to why we would anticipate that socialism would reduce inequality are not as closely related to the DGI model. Examples include the notion that, because socialist elites are highly proletarianized, policy will favor the lower classes and less inequality; because people (the central wages board), not the market, are responsible for one's income, the state is more apt to maintain low inequality in anticipation of discontent among the masses if it did otherwise; and, because elites are obliged to adhere to egalitarian wage policy because, from the standpoint of traditional socialist ideology, this is expected (Parkin, 1971; Stack, 1976:152–80).

Table 1. Effects of DGI, GNP/Capita, and the Rate of Economic Growth on the Degree of Income Inequality (Using Wilczynski's Estimates of Socialist DGI) (N = 32)

Variable	Regression Coefficient	Standard Error of Coefficient	Computed Value of Student's T	Beta Coefficient
DGI	−0.003	0.001	−4.589**	−0.694
GNP/cap	−0.000	0.000	−1.800*	−0.219
EG	−0.004	0.010	−0.377	−0.057
Intercept	.549218			

$R^2 = .59.$
$\bar{R}^2 = .55.$
F = 13.5, 3/28 df.

* = statistically significant at the .05 level.

explained. These findings lend support to those who hold that socialism is the main determinant of destratification (Parkin, 1971; Stack, 1976).

SOCIALIST INEQUALITY

Jackman holds that the data on income distribution in the socialist nations are not comparable to those for the capitalist nations. At one point, he asserts that the data I use overstate the degree of equality in the socialist countries. The opposite is probably more accurate. He makes no mention of the fact that all of these data will, simply by definition, make the socialist nations look comparatively inegalitarian when compared with similar data from the capitalist nations. The income data from the capitalist nations routinely omit major sources of property income such as capital gains. Data from the capitalist nations exaggerate the degree of equality. Since property income is virtually eliminated in socialism, if all *else* is equal, socialist nations will have substantially less inequality. As Lundberg (1969) points out, property-based income is one of the backbones of inequality in capitalist nations. For those with incomes of over one million a year, approximately 90% comes from property, not wages. The importance of property income in maintaining inequality can be measured to an extent by comparing the degree of inequality before a Communist take-over with that after the rise of Communists to power. For example, the degree of inequality in Yugoslavia, in 1938, was .352 compared with levels in the .250–.280 range in the 1960s (Vinsi, 1967; Michal, 1973).

I am puzzled over Jackman's error wherein he senses discrepancies between the U.N. data and Michal's (1973) data. The problem is that he selects inappropriate U.N. data (United Nations, 1967:Table 9.20). The relevant discussion on these data (United Nations, 1967, chap. 9:24–6) notes that they refer to the per capita distribution of income in Hungary and Poland. These are not the kinds of data we want for our investigation. This is why Jain (1974) used data from another part of the book (United Nations, 1967, chap. 8:71) for his calculations on measuring inequality. For Hungary, these estimates are .229 (1955), .202 (1958), and .208 (1964). These more appropriate U.N. data are, in fact, well in line with Michal's estimates of .226 (1960) and .240 (1964). If anything, the Michal data provide more conservative estimates of socialist equality. If Jackman had used the appropriate U.N. tables, he would have found the opposite of

Table 2. The Effects of DGI, GNP/Capita and the Rate of Economic Growth on the Degree of Income Inequality with DGI Measured as a Dummy Variable (N = 32)

Variable	Regression Coefficient	Standard Error of Coefficient	Computed Value of Student's T	Beta Coefficient
DGI	−0.195	0.036	−5.418**	−0.721
GNP/cap	−0.000	0.000	−2.786*	−0.312
EG	−0.006	0.009	−0.652	−0.087
Intercept	.501963

$\bar{R}^2 = .61.$
F = 17.4, 3/28 df.

what he asserts. I was certainly not out to select data to make the socialist countries appear less unequal than they are. For the same reasons, Jackman's comment on Poland is also an error.[5]

In the case of the data for Czechoslovakia, the U.N. (Table 9.19) provides a quartile ratio of 1.62 for 1959. I do not see what basis Jackman has for asserting that this is at odds with the Michal data, since Michal does not even provide the data necessary for such a comparison. Furthermore, the Ginis based on the U.N. data are between .188 and .200 (Jain, 1974). The Michal estimates are between .195 and .199. Again, Jackman's criticisms seem to be based on some misunderstanding of the data involved.

In an unnecessary fabrication, Jackman discusses the pitfalls of my supposed use of data based on a single city in Poland—Lodz—to estimate inequality in the country, as a whole. I simply did not use these data (Szafnicki, 1971:39). Instead, I used the more appropriate data for Poland as a whole (Szafnicki, 1971:43). The Gini for Lodz was .166 while the Gini for Poland was .234. Jackman appears to be guessing which data I used. His guesses are wrong ones.

With respect to the data for Hungary, Jackman implies that they are not representative of the entire income distribution since they apply to state sector employees. He provides no evidence for this assertion. However, available information (on the degree to which the degree of inequality in the state sector is a reliable approximation of overall inequality) indicates that the former is a good predictor of the latter. For example, McAuley's (1977) estimates of the total degree of inequality in the USSR are decile ratios (D9/D1) between 3.04 and 3.08. These can be compared with his decile ratio for the state sector alone which is 3.00. While there is a slight difference in these figures, I do not see it as "undermining" the results of the investigation! We might note that the corresponding decile ratio for the United States is approximately 14.0 (Kolko, 1970:14). Nevertheless, if we omit Hungary from the analysis—as I did in a separate analysis—the results support the model just as solidly as before.

Still, Jackman is correct in stating that there is some variability in the estimates of socialist inequality. One way of assessing whether or not this variation "undermines" our results is to use the estimates (excluding the noncomparable data on the per capita income distribution) that provide the highest degree of income inequality for the socialist nations for the 1959–1965 period. In this manner, we are probably exaggerating the degree of socialist inequality. For example, we will use the estimate of .244 for Bulgaria instead of the original approximation of .215.[6] As a further precaution, we will use Wilczynski's (1977) estimates of socialist DGI. The results of the regression analysis using the maximum Ginis for the socialist nations are given in Table 3. Even with these exaggerated estimates of socialist inequality, the results of the analysis are nearly the same. DGI is again the most important variable. The level of development is significant while the rate of growth is not. The model explains almost as much of the variance (53%) as in the original work (57%).

CAPITALIST DGI

The final criticism of Jackman is that if we restrict the DGI model to capitalist nations, DGI and inequality are not significantly related. However, he provides no rationale about why this should be the case. In particular, should we attempt to reformulate DGI theory?

---

[5] Again, these data are from the wrong table (United Nations, 1967, Table 9.20) which provides data on the per capita distribution. Jackman should inspect other data (United Nations, 1967, chap. 8: 71). The estimates of inequality for Poland, based on these data, are between .252 and .253 (Jain, 1974). The estimate from Michal's work is exactly the same: .253.

Firebaugh also makes numerous errors and/or guesses in his handling of income inequality data. For example, he uses inappropriate estimates for Poland and Romania consisting, respectively, of .17 and .23 (see his Appendix). His assertion that I apparently "overlooked" comparable data on some 48 nations is quite inaccurate. The data in the Jain source, as Jain cautions, are marked by many serious problems of comparability. While Firebaugh reports a correlation of .96 between the Ginis of approximately two dozen nations which are available in both the Paukert and Jain sources, this is not surprising and does not necessarily mean that the Jain data are reliable. For these two dozen nations, Paukert and Jain used many of the same data sources! As Jain (1974:1) states:

> In preparing this compilation we have been greatly reinforced in our reservations on the accuracy of such data. . . . The reader is therefore cautioned that the data reported in this paper are not in any sense presented as reliable or as best estimates.

This is why I restricted my capitalist sample to the data adjusted by Paukert (1973).

[6] The data for Bulgaria are taken from Jain's calculations which were based on the appropriate United Nations data (United Nations, 1967, chap. 8:71). In my original article, I neglected to give the source (Grindea, 1974) of the data on Romania.

Table 3. Effects of DGI, GNP/Capita and Economic Growth on Income Inequality (Using Maximum Ginis for the Socialist Nations (N = 32)

Variable	Regression Coefficient	Standard Error of Coefficient	Computed Value of Student's T	Beta Coefficient
DGI	−0.003	0.001	−4.425**	−0.679
GNP/cap	−0.000	0.000	−1.863*	−0.230
EG	−0.004	0.010	−0.398	−0.061
Intercept	.547687			

See notes to Table 1.
$R^2 = .58$.
$\bar{R}^2 = .53$.
F = 12.8, 3/28 df.

If so, how so? Is the DGI/full employment connection deficient? Or perhaps we should, as I indicated in my paper, focus on the type of government spending and not just on the quantity (Stack, 1978a:883). Jackman does not engage in any theoretical discussion of why the DGI model may not work for the capitalist sample. Instead, he seems interested only in using the results of his "quickie" empiricism to discredit and disprove the DGI model. In similar fashion, in his Table 1, Firebaugh notes a discrepancy in the correlations between DGI and inequality.[7]

The need for theoretical reformulation of DGI theory, however, may be premature. First, Jackman's own analysis fails even to mention a problem of near severe multicollinearity, which makes the results of his regression analysis quite tenuous. Jackman, as does Firebaugh, fails to report the zero-order correlation between capitalist DGI and the level of development (r = .43). According to the Klein test for severe multicollinearity, if rij > R, severe multicollinearity is present, and the results of regression analysis are meaningless (Dutta, 1975:150). Jackman's adjusted multiple correlation is .46, indicating the near presence of severe multicollinearity. His results are to be taken with great caution.

I recently came across some data which allow us to explore the capitalist DGI/inequality relationship for a much larger sample of 53 capitalist nations.[8] The zero-order correlation between DGI and inequality is significant and in the expected direction ($r = -.30$, $p < .025$). This was not the case in Jackman's relatively small sample of 22 nations. The findings for the larger sample support the DGI model. Unfortunately, we were unable to engage in a meaningful regression analysis of the effect of capitalist DGI on inequality because there was a severe problem of multicollinearity between level of economic development and DGI. For this reason, great caution should be exercised in further investigations on the subject. We suggest that DGI and development be analyzed separately.

MODEL SPECIFICATION

Firebaugh holds that a major problem in my work is that the model is misspecified—that is, if one adds a measure of political democracy to the analysis, the DGI/inequality relationship vanishes whether we use my data or his "corrected" data which omit all of the socialist nations from all calculations involving DGI. He sees my omission of an index of politics as "strange" since in my work on inequality in *capitalist* nations I have stressed the need for such an index (Stack, 1978c). There are two devastating problems with Firebaugh's naive forcing of his western measure of democracy into the analysis.

First, being a western measure it discriminates against one-party political systems. Second, even if it did not discriminate against such systems, there is such a severe problem of multicollinearity between it and DGI that the results of the regression analysis are meaningless. Firebaugh's index uses a measure of party competition, based on the number of parties, in which the higher the number of parties, the higher the competition and democracy. Because all of the socialist nations have only one party, it is then assumed that they are, therefore, low in democracy. Problems associated with this index include the notion that there can be competing factions within a single party. Firebaugh's index of democracy also contains an index of electoral irregularity based on Mackenzie's notions of what constitutes "regular" (e.g. honest, competent administration to run the elections) elections (Taylor and Hudson, 1972:23–5). As Taylor and Hudson (1972:25) point out, this index has been under attack for some time. Critics hold that the Mackenzie criteria are not relevant to nonwestern systems and that the coding is uncritically biased against the socialist nations. It seems quite irresponsible of Firebaugh not to mention these debates.

---

[7] Likewise, by omitting all socialist nations from all regression calculations involving DGI and income inequality (the SPSS pairwise deletion of missing-data procedure), Firebaugh finds no evidence in his Table 3 for the DGI theory as it applies to capitalist nations.

[8] The data on DGI are taken from World Bank (1976:440–6). They refer to total government expenditures as a percent of gross domestic product. The data on income inequality are taken from Paukert (1973).

The second problem with the Firebaugh index is that the socialist nations all have very low scores on it—just as they all have very high scores on the DGI index. Statistically, the two scales measure the same thing, multicollinearity is present, and the results of all three of Firebaugh's new "specifications" are meaningless. I did not include an index of political democracy because I could not find one that avoided the problems of bias against the communist nations and the problem of multicollinearity. The class composition of parliament and/or elites—such as the politiburos and cabinets—avoids the first problem; but, because communist political bodies are far more representative of the lower class than are capitalist bodies, the DGI and class-composition variables are marked by the problem of severe multicollinearity (Stack, 1976).

Firebaugh then proposes a second respecification, including not only his invalid measure of politics but also an invalid measure of state strength in world economy. In a rather sloppy fashion, he borrows, from his ASA conference paper, his index of political performance, using it to measure state strength in world economy (Olsen and Firebaugh, 1975:8). His index of political performance has essentially nothing to do with a state's power in world economy. His index measures four dimensions of political performance: the degree of civil violence; legislative effectiveness, which has to do with the extent to which the legislature's power is independent from that of the executive branch; the degree of modernity in the administrative branch; and government size, which is measured as government expenditures per capita (Olsen and Firebaugh, 1975:8). As I have pointed out elsewhere, in a work Firebaugh claims to have read, state strength in world economy needs to be measured in terms of tariff and trade policies—or in terms of other relevant indices, such as the rules and regulations controlling foreign capital in a nation (Stack, 1978c:271). Far from satisfying this criticism, Firebaugh creates a useless index of state strength. Firebaugh's index fails to distinguish between two very different variables: state strength in world economy, and political performance.[9]

CONCLUSION

Jackman's criticisms are largely restricted to the problem of measurement errors. If we address this problem where it, in fact, exists—by substituting the most comparable and appropriate data—the DGI model is still supported. Jackman's one theoretical criticism (that a Keynesian model is inappropriate for socialist economies) is based on a misunderstanding of DGI theory which can draw on a number of perspectives besides Keynesianism. Relevant DGI mechanisms in socialism, for example, include the coordination of savings and investment decisions, the redistribution of income gains from the technological sector to the nontechnological sector, and the manipulation of wage rates by national wages boards. All of these DGI mechanisms are lacking in capitalism. All are associated with the abolition of private corporate property and "ridiculous" levels of government spending in the high nineties. One must remember that government spending is just *one* example of a DGI mechanism. Jackman's critique has serious problems associated with it, and one wonders if my own critical review of Jackman's work may have motivated his hasty criticisms (Stack, 1978b).

---

[9] Firebaugh raises a number of other criticisms which have numerous problems. While some of the effects of the model work backward in time if we substitute available data for alternate years, such as that for GNP, we find the same results. In cross-national research, the inavailability of data often leads to this problem. Indeed, Firebaugh's own alternative specifications have this problem (e.g., he uses an index of electoral irregularity which is *circa* 1965 and which comes after the *circa* 1960 Ginis). Other problems are germane to much research. These problems include a lack of investigation of reciprocal effects and a truly systematic measure of economic inequality. With respect to the latter problem, income researchers might feel better about their supposedly "primitive" attempts to measure the concept of inequality if they read Firebaugh's own work which uses passenger cars per capita to measure income distribution (Olsen and Firebaugh, 1975:9)! Firebaugh's criticism that I omit the major Keynesian variable of unemployment from my discussion of DGI theory suggests to me that he fell asleep while reading page 883 of my original article. I find Firebaugh's cursory view of 1950–1970 trends in inequality and DGI unconvincing. His largely unsubstantiated premise that income inequality is a constant of sorts which defies changes in societal organization does not fit well with much available data. For example, data from the Japanese ministry of finance (personal communication) indicate that inequality fell from .346 in 1955 to .281 in 1972. Jain's data for Finland indicate an increase in inequality from .395 in 1952 to .454 in 1962. In addition, the delineation of a simple bivariate relationship, over time, should be supplemented with control variables to unmask possible spurious and suppressed relationship. One of Firebaugh's concluding remarks—that I give no evidence that redistribution occurs because of taxation, not because of full employment policy—is quite a blunder, since any income inequality researcher knows that all of the relevant data refer to the pretax distribution of incomes. Hence, the variation in inequality in the data is necessarily due to factors outside the tax policies of the nations involved.

Firebaugh's claims about missing-value cards are simply erroneous rumors. His "corrected" data which he presents in his tables are to be viewed with great caution because they leave all the socialist nations out of all the critical DGI calculations. In a similar fashion, his alternative specifications are meaningless—given such considerations as their use of biased measures of democracy, which are inappropriate for a sample containing socialist nations. Firebaugh's fabrications include his paragraphs on how I failed to deal with the key Keynesian variable of unemployment. Many of his other criticisms, such as "cross-sectionalism"—failure to test the model with unavailable time-series data—and his long tangents on needed refinements in measuring economic inequality (even though the needed data are not available) might be viewed as impossible dreaming.

In general, I found both critics to be preoccupied with attempts to discredit the new DGI approach. Their resort to such minor means as fabrications, guesses, mundane empirical problems, inappropriate data analyses, and countertheoretical arguments serves only to reveal their ignorance of how DGI theory can be applied to socialist economic systems.

SOCIOBIOLOGY AND PARADIGMS IN EVOLUTIONARY THEORY

(COMMENT ON QUADAGNO, ASR, FEBRUARY, 1979*

While Dr. Quadagno's (1979:100–8) paper on evolutionary theory and sociobiology is a useful contribution to the growing literature on the subject, we find several of her major arguments to be either in error or somewhat misleading. Similarly, the conclusion drawn from her analysis seems to be severe and not justified by the arguments presented in her paper. First, we will examine alleged errors in the logical structure of sociobiological theory.

Tautology and Evolutionary Thought

Quadagno maintains (p. 104) that sociobiologists introduced tautological reasoning into the evolutionary model. This is a somewhat surprising charge coming from someone apparently knowledgeable in the history of Darwinian thought. It is not clear how sociobiology utilizes any tautology not present in Darwin's original formulation. Quadagno mentions (p. 102) that Darwin adopted Spencer's term, "survival of the fittest," in later editions of the *Origin of Species*. It is interesting that Quadagno considers the sociobiological concept, "maximization of inclusive fitness," (Alexander, 1975; Barash, 1977; Wilson, 1975) to be tautological, and yet does not find "survival of the fittest" to be equally so.

A tautology can be derived from Darwin's and Spencer's phrase: survival is the criterion of fitness and fitness results in survival (Hull, 1974). If, in turn, Darwin's notion is tautological, the implication is that not only sociobiology can be rejected as logically inadequate, but all of Darwinian evolution as well.

The charge of tautology has been leveled at Darwinian theory, even very recently (Gould, 1976). If fitness in Darwin's sense is defined in terms of survival, the theory is reduced to a tautology. However, assertions of Darwinian fitness must always be made in reference to an organism or trait in the context of a changing environment (Hull, 1974:67; Scriven, 1971:215). Gould (1976:26–30) argues that survival is an expression of a superior a priori trait and that it is the improved trait that is the independent criterion of fitness in Darwin's sense, not survival per se (cf. Dobzhansky, 1955). As Mayr (1976:13) notes, the possession of certain genetic characteristics determines evolutionary success, in that an individual with those characteristics is more likely to reproduce than those without them. Thus, "the process of natural selection can be thought of as the comparison of variant structures in terms

---

We would like to thank J. Frank Cassel and an anonymous *ASR* reviewer for reviewing earlier drafts of this comment.

of their survival value and choosing the best" (McCleery, 1978:382).

But if Darwin's formulation is not truly tautological, what of sociobiology? In order to assess whether sociobiology rests on a tautology, some clarification of "fitness" is necessary. Darwin defined fitness as being well adapted and any trait that helped an organism to survive increased its fitness (Mayr, 1976:74). However, sociobiologists and population geneticists do not use fitness in this very broad sense.

Mathematical geneticists Wright, Haldane, and Fisher redefined fitness to mean the contribution an individual makes to the gene pool (Mayr, 1976:316). According to Mayr (1976:74), "[f]itness under the new definition can be due either to the superior fitness in the Darwinian sense or to reproductive advantage that does not add to the adaptedness of the species." Adaptiveness, therefore, should not be equated with fitness in the genetic sense. An adaptation is any genetically determined characteristic that increases an organism's ability to cope with its environment (Ricklefs, 1973). Fitness, on the other hand, is ". . . a value free algebraic parameter that measures the contribution made by hereditary determinants to the differential reproductive rate of organisms" (Stent, 1978:213). Adaptiveness and fitness are conceptually linked, but distinct—a point not always observed in the literature.

In a correct sociobiological sense, fitness refers only to an individual's contribution to the gene pool, directly and through kin. The statement that organisms tend to act to maximize their fitness means only that they "seek" representation in the gene pool through reproduction, altruism, etc. Behaviors that promote this representation—i.e., that increase fitness—are selected for by environmental pressures over those that do not. In this matter sociobiology is orthodox Darwinian theory (Ruse, 1978:358). An individual can be well adapted but unfit if it fails to reproduce.

If sociobiology were truly tautological, presumably it would be unfalsifiable. Nevertheless, critics (e.g., Sahlins, 1976) have, simultaneously, accused sociobiology of being tautological and attempted to falsify it (Ruse, 1979). It is possible to make behavioral predictions based on sociobiological tenets and to empirically evaluate those predictions. Then, if found false, and if acceptable alternative explanations cannot be developed, those predictions can be rejected as false (Krebs and Davies, 1978). This would not be the case, however, if sociobiology were tautological.

The upshot of this is that neither Darwin's formulation nor sociobiology's is tautological. If there were a tautology present, it has been in the theory since Darwin's time, and not introduced by sociobiologists as asserted by Quadagno.

Maximization of Genetic Fitness[1]

The treatment of the maximization of genetic fitness in Quadagno's (1979:106ff.) paper is also problematic. While Quadagno treats fitness as denoting an *outcome*, fitness, in fact, refers only to a *process*, or *tendency*. Indeed, her quote from Alexander (p. 104) refers to a continuing process, *not* an outcome. Barash (1977:33) notes that "all fitnesses are relative not only to other traits but also to the environment in question." Quadagno's paper seems to misunderstand this point. Sociobiologists do not argue that species ever achieve maximal fitness in an ultimate sense but, rather, only that natural selection is a directional influence towards increasing genetic fitness.

In this regard, Quadagno's (1979:104) paper exhibits conceptual confusion. She introduces the term, "adaptive fitness," a term not found in sociobiological literature. Additionally, she fails to use fitness in the sense of genetic contributions to the gene pool. While her introduction of this term may serve her argument, it obscures the distinction between adaptiveness and fitness. She then attempts to equate the principle of the maximization of genetic fitness with "maximal adaptiveness" (p. 104), further confounding adaptiveness and fitness. Her term implies an ideal phenotypic adaptation, an implication not found when fitness is used in its sociobiological sense. Sociobiologists, and evolutionists in general, don't normally look at the overall fitness of an organism but, rather, look at the fitness of particular traits of an organism in a given environment (Hull, 1974).

In attempting to demonstrate how sociobiologists violate Darwin's emphasis on minimum reproductive advantage with their "preoccupation with maximization" (p. 103), Quadagno misinterprets the use of the concept. She cites Williams (1966:132) in this regard, who writes, "[t]he reproduction of every individual is designed to maximize the number of its successful offspring." The key word in that phrase is "successful"—i.e., offspring who themselves live to reproduce. Maximization refers to an optimum. Organisms do not necessarily attempt to produce a maximum number of offspring, nor does sociobiology imply that they do. An organism maximizes its genetic fitness by producing an optimum number, with optimality dictated by local environmental circumstances. An organism can reduce its genetic fitness by producing too few offspring *or* too many, depending on a host of ecological variables. This is central to the process of natural selection. By "maximizing" its genetic fitness, an organism gains an advantage over its conspecifics who may fail to produce that optimum number; but that advantage may be only a slight one. Therefore, we do not consider sociobiology's "preoccupation" with maximization to violate Darwin's position.

---

[1] Sociobiologists use the concepts terms, "inclusive fitness" and "genetic fitness," neither of which is used systematically in Quadagno's paper. Genetic fitness refers to the "contribution to the next generation of one genotype in a population relative to the contribution of other genotypes" (Wilson, 1975:585). Inclusive fitness is defined as the "sum of an individual's own fitness plus all its influence on fitness in its relatives other than direct descendants . . ." (Wilson, 1975:586). Neither concept makes any implication of the ultimate adaptiveness of a phenotype as suggested by Quadagno.

It is interesting that Quadagno (1979:102) does not see a maximizing principle in the phrase, "survival of the fittest." Not only does it argue that the *fit* survive, it also clearly states that the fit*test* survive. In fact, in either Darwin's or sociobiology's formulation, fitness is relative. To maximize its fitness, an organism has to gain only some genetic advantage over conspecifics.

Adaptation and Nonadaptation

Quadagno (1979:104) argues that sociobiologists ignore the complexities of the mechanisms of evolution and concentrate on adaptation via natural selection. She asserts (p. 104) that "[n]o single mechanism accounts for all evolutionary change . . ." and goes on to note that many differences between organisms can be " . . . attributed to *nonadaptive* differentiation" (emphasis hers). Quadagno identifies (p. 104) some other mechanisms of differentiation such as genetic drift, migration between gene pools, and recombination. It should be noted that anything that causes genotypic—and, hence, phenotypic—variation is, in turn, acted on by natural selection, including the random factors listed by Quadagno. Therefore, it is not clear how sociobiology's interest in adaptive factors in evolutionary change distorts either evolution or "the actual state of affairs in the real world" (Quadagno, 1979:105). And, while sociobiologists are most concerned with behavioral adaptations of organisms, it would appear that they have not ignored other factors in evolution (e.g., Wilson, 1975:21–4, 64, 66).

It should not be surprising that the main concern of sociobiologists is the adaptations. As Ruse (1979:115) points out, evolutionists today more readily assume adaptive advantage for traits than they did twenty years ago. Darwin did not develop his particular formulations by assuming that the traits he observed in various organisms were *nonadaptive*.[2] While the explanation of possible nonadaptive traits has become a point of interest for some evolutionists, in the development of Darwin's theory the concern was clearly with the adaptive significance of traits. It would seem premature to accuse an emerging theory of ignoring one factor or another, when it has only begun to enter its period of "normal science" (Kuhn, 1970).

One other point in Quadagno's (1979:105) discussion of this requires some clarification. She writes, "[f]actors such as nutrition, toxins, accidents and learning experiences introduce phenotypic variance that goes beyond the control of the genotype, often reducing the adaptiveness of the organism." While she implies that such factors are nonadaptive, it would appear that accidents, nutrition, and toxins are simply part of the selection pressures that organisms face. In other words, these are components of natural selection as they act differentially on variations in individuals. It is true that such factors may reduce phenotypic adaptability (Quadagno, 1979:105) and, ultimately, genetic fitness; but there is no reason why the converse cannot be equally true—i.e., that such factors affect, positively, the fitness of some genotypes. Quadagno's major problem in this section stems from her attempt to take a concept referring to gene frequencies—i.e., fitness—and to improperly extend it to refer to a "maximally adapted" phenotype, an extension not found in sociobiological literature.

Altruism

The problem of altruistic behavior, as discussed by Quadagno (1979:103), is in need of elaboration. Why some organisms exhibit altruistic behavior has been one of the major problems of evolutionary theory and it is unquestionably a problem of interest to sociobiologists.[3] One of the explanations offered in sociobiology, the theory of kin selection, is rejected by Quadagno in the course of her rejection of the notion of reciprocal altruism. We would first raise the question: how *does* evolutionary theory explain altruistic behavior in nonhuman animals—if not by kin selection or a related concept? An early reference to the principle of kin selection appears in Darwin's *Origin of Species* (Wilson, 1975:117), indicating that kin selection is not a particularly new concept. The kin selection hypothesis has been successful in explaining altruism in a number of social species and is a plausible theory being offered in regard to certain forms of animal behavior. The sociobiological concept of parental manipulation (Alexander, 1975) also has been found useful in explaining certain forms of animal behavior, although it is not considered by Quadagno.

---

[2] Quadagno is in error when she states (p. 103) that Darwin studied fossils on the Galapagos Islands. He studied variations among living species of finches on the various islands of the archipelago (Barlow, 1933:438).

[3] We are in disagreement with Wilson (1975:3) that altruism is the central problem of sociobiology. His own work would indicate that it is but one of many points of interest to sociobiology.

The idea of reciprocal altruism (Trivers, 1971) is problematic and we are in agreement with Quadagno as to its lack of utility in sociobiology. We find it of little use because, conceptually, it does not seem to be distinct from more general notions of sociality. The examples of reciprocal altruism given by Wilson[4] (1975:120) may be taken as a case in point. Quadagno seems to suggest (p. 107) that, by rejecting reciprocal altruism as an explanation, ipso facto all sociobiological explanations of altruism can also be rejected. Trivers' concept is scarcely a central part of the sociobiological explanation of altruistic behavior—so, by its refutation, the power of kin selection and parental manipulation hypotheses are not weakened. However, we neither suggest that kin selection or parental manipulation are suitable for explaining all forms of altruistic behavior nor have the space to discuss the complexities of their application to human groups.

Evolutionary Principles

In discussing evolutionary principles, Quadagno (1979:107) characterizes sociobiology as suggesting that organisms are always progressing toward an optimum phenotype. This interpretation is at variance with Wilson's position, even on the page that Quadagno cites from him to support her contention (cf. Wilson, 1975:24). Wilson discusses "an equilibrium case," in which organisms have reached a steady state with regard to a given trait, even though theoretically they could evolve a better-adapted phenotype. Evolution of the trait does not continue toward some ideal value but, rather, it is halted in an intermediate state, due to opposing selection factors operating on secondary characteristics of that trait.

When sociobiologists do discuss optimums, intrinsic in the notion is the principle of evolutionary compromise (Wilson, 1975:131–2). In this case, an "optimum phenotype" is that which exists when various selection pressures strike a balance and evolution reaches a stabilizing state (Wilson, 1975:131). An optimum state is a compromise and a temporary condition. It should not be confused with an ideal or "maximally adapted" phenotype, as Quadagno (1979:105) implies. Optimality in sociobiology simply refers to a "temporarily stabilized" state (Wilson, 1975:132) and is the result of the play of various selection pressures from a changing environment.

A further point in Quadagno's (1979:105) paper involves an issue that can be by no means resolved in this short essay. That is the problem of the applicability of sociobiology to the study of human social behavior. Quadagno consistently characterizes nonhuman social behavior as "simple" and human social behavior as "complex." To describe nonhuman social behavior as necessarily simple is, at best, anthropocentric. Some of sociobiology's empirical "successes" have been in the analysis of very complex insect societies (Wilson, 1975) as well as in the analysis of relatively large primate troops (e.g., Hrdy, 1977). There are levels of human social organization that are less complex than such nonhuman social aggregates.

The real issue in a human sociobiology—one not directly addressed by Quadagno—is the degree of genotypic involvement in human behavior and the plasticity, or the lack of it, in those behaviors. One cannot simply assume that there is no genotypic involvement in human behavior. A necessary step in the development of a human sociobiology will have to be the determination of the role of genotype in human behavior, and in which behaviors genotype plays a part. Most of what sociobiology has proposed in this area has been, of necessity, speculative (e.g., Barash, 1977; Daly and Wilson, 1978; Wilson, 1975; 1978a). However, some recent studies are beginning to provide at least some suggestive preliminary evidence of the role of genotype in some human behaviors (Freedman, 1978; 1979;[5]

---

[4] Wilson (1975:120) does cite several examples of behavior that may be considered as examples of reciprocal altruism, in contradiction to Quadagno's assertion. However, the examples cited do not seem to be distinct enough to be considered as anything but examples of general sociality. Packer (1977) does offer a clear empirical case of primate behavior best described as reciprocal altruism.

[5] Freedman (1979) summarizes 50 empirical studies applying sociobiological principles to the study of humans.

Loehlin and Nichols, 1976; R. Wilson, 1978). At the same time, we recognize that some sociobiologists have been overzealous and incautious in their "biologicizing" of human social behavior and have been justifiably criticized.

Summary and Conclusions

We have argued that there is no inherent tautology in sociobiological reasoning and that it is logically consistent with Darwin's version of natural selection. The principle of the maximization of genetic fitness does not violate Darwin's formulation but, rather, simply extends it to behavior. In this instance, Quadagno (1979:104ff.) has reinterpreted the concept and has apparently confused a process (maximization of genetic fitness) with an ideal end state (maximal phenotypic adaptiveness). Maximizing genetic fitness refers only to achieving a certain gene representation in the gene pool—via successful offspring and siblings not producing a maximum number of offspring, irrespective of their survival—unless the latter is the evolved strategy that insures gene representation as it does in some species. Reproductive strategies are species specific.

We have attempted to show that sociobiologists are aware of random and nonadaptive factors in evolution. However, as with most evolutionary theory, sociobiology is more concerned with how traits are adaptive and to criticize it for that is to ignore the basic premise of Darwinian evolution.

We have suggested that Quadagno's treatment of the problem of altruism is, in some ways, in error. She correctly criticizes the notion of reciprocal altruism but attempts to discredit other sociobiological explanations of altruism by association. The kin selection hypothesis as an evolutionary explanation of altruism has been found to have analytic utility for nonhuman animals.

Given these suggested weaknesses in her presentation, we find Quadagno's (1979:108) claim that "sociobiology is not applicable to the study of human social behavior" to be severe and unwarranted, particularly at this early stage in the development of sociobiology. We are in agreement with Quadagno's assertion that sociology is in no immediate danger of being replaced by sociobiology. As Wilson (1978b:xii) notes, "[c]ontemporary general sociobiology might at best explain a tiny fraction of human social behavior in a novel fashion." We would argue that, although sociobiology as a paradigm of behavior is in its infancy, it has provided an interesting, if controversial, set of postulations regarding human social behavior. The outright rejection by Quadagno of sociobiology, at least in its relevance to humans, is very similar to the "scientific" response to Darwin's *Origin of Species* by his contemporaries (Hull, 1978). Hull notes that Darwin's theory faced many of the same methodological and theoretical critiques as sociobiology.

It appears that some sociologists are attempting to hold sociobiology to standards of scientific rigor that few of their own theories would survive. As Hull (1978:145) writes, "[t]he trouble with the methodological objections raised against sociobiology is that the standards from which they flow are applicable only to theories as finished products and they are being used to assess a newly emerging theory." It is ironic that a discipline that uses its youth as a defense of the inadequacy of some of its theories would so readily attack a paradigm that has barely settled on its major principles or methods.

In its current state of development, sociobiology requires further conceptual and methodological elaboration and clarification. That some of sociobiology's concepts may be obscure should not be surprising.[6] As Hull notes (1978:145), ". . . this state of affairs is common in science" and, as such, does not justify a call for the rejection of sociobiology.

We contend that the charges brought by Quadagno (1979:106ff.) against sociobiology are little different from the charges that have been, or could be, brought against Darwin's theory. We have also tried to demonstrate that, in general, they are unwarranted. Paradigmatically, sociobiology does not represent any radical discontinuity with Darwinian principles. Rather, it extends them, in combination with population genetics, to the study of social behavior. Calls for the rejection of a theory are commonplace in the history of science. Darwin was subjected to them and has been vindicated (Hull, 1978; Mayr, 1976). Quadagno's conclusion of the inapplicability of sociobiology for human behavior suggests the premature closure of sociology and is not likely to serve any scientific purpose. Hypotheses such as those offered by sociobiology must be entertained, often before we have ways of testing those hypotheses or before we know if they can be tested (cf. Kaplan, 1964). While careful evaluation of sociobiology must continue in sociology, calls for its rejection are not justifiable at this stage in sociobiology's development.

---

[6] Ruse (1973:49) indicates it is not unusual, in evolutionary theory, to find instances of "suggestions, hypotheses, extremely weak inductive inferences and frequently outright guesses." In the development of a science, particularly one just emerging such as sociobiology, there is a need for open-ended concepts, concepts open to alteration as new data become available (Skolimowski, 1974). Critiques such as Quadagno's are useful in pointing out areas in need of clarification.

REPLY TO BOLIN AND BOLIN*

In commenting on my critique of sociobiology, Bolin and Bolin propose a series of arguments, some perhaps valid, some based on a misunderstanding of points made, and a few containing clear misrepresentations of my position. Since the central theoretical problem of sociobiology has been to explain altruism, I will begin with this issue.[1]

---

* Direct all communications to: Jill S. Quadagno; Department of Sociology; The University of Kansas; Lawrence, KS 66044.

As I stated in my original essay, kin selection and reciprocal altruism provide mutually exclusive and contradictory hypotheses to explain the same phenomenon. The explanation of reciprocal altruism by selection has proven difficult for sociobiologists, and Bolin and Bolin (with some vacillation on their part) join me in rejecting it. Bolin and Bolin state that I also reject the theory of kin selection. Since they do not refer to a specific page in my paper, it is impossible to determine where they find my rejection of this concept. In fact, no such statement appears.

The fact that I do not reject kin selection does not mean that it is not problematic and still a source of debate, even among "known" sociobiologists. For instance, Dawkins (1976:101–2) disputes Wilson's (1975) presentation of kin selection as a special case of group selection, arguing instead that it is a special consequence of gene selection. He also chastises Wilson for excluding offspring in his definition of kin selection, for offspring have the same genetic relationship to an individual as siblings ($r = ½$). Their exclusion ignores Hamilton's (1964) argument that the distinction between kin and nonkin is not hard and fast but a matter of mathematical probability.

Parental manipulation, a theory which I ignored in my original essay because it was not directly relevant, has been posed as an alternative evolutionary cause of altruistic behavior, independent of straightforward kin selection (Alexander, 1975). It has been accepted by some and rejected by others. For instance, Dawkins (1976:148) states, "Alexander's conclusion that there is a built-in advantage on the parent's side in the conflict of interests is not correct."[2] I will not attempt to summarize the debate here but will leave the topic open as a possible source of explanation of some forms of altruistic behavior in nonhuman animals.

If we then accept kin selection and parental manipulation as potentially valid explanations of altruistic behavior toward relatives, we are still left with the original dilemma of how altruism toward nonkin (which, by definition, reduces "personal fitness") could possibly evolve by means of natural selection. Bolin and Bolin do not deal with this problem at all. More important is the fact that my paper was quite specifically a critique of the application of sociobiology to complex human social behavior. I do not disagree with Bolin and Bolin that kin selection has "analytic utility for nonhuman animals." However, I would question its extension to humans and, apparently, Bolin and Bolin would also.

This brings me to the second issue, the presumed ability of sociobiologists to identify the biological basis of complex human social behavior. On this topic, Bolin and Bolin misrepresent my position. By using complex (as opposed to simple), my allusion was to the array of human social behaviors—referred to by Wilson and other sociobiologists—which can purportedly be explained by sociobiological theory. Among these, to name a few, are deceit, parent/child conflict, the self-centeredness of young children, the peer-group orientation of adolescents, religion, and the altruism of the living saint, Mother Theresa (Barash, 1977; Trivers, 1972; 1974; Wilson, 1975; 1978). I did not mean to imply, as Bolin and Bolin suggest, that nonhuman animal behavior was not complex but, rather, that sociobiology is incapable of calculating the genetic basis of complex human behavior. This does not signify that there is no genotypic involvement in human behavior, only that there is no way of measuring it.

Third, there is the question of whether sociobiological reasoning is tautological. The answer depends partly on the definition of two terms, "adaptation" and "fitness." Interestingly, in defining these concepts, Bolin and Bolin do not quote sources identified as mainstream sociobiologists. Thus, they are able to keep the terms analytically distinct. In the definition they use, an adaptation is "any genetically determined characteristic that increases an organism's ability to cope with its environment," whereas fitness refers to "the contribution made by hereditary determinants to the differential reproductive rate of organisms." In contrast, the sociobiological usage confounds the two terms. For instance, Barash (1977:33) states that an adaptation is "any evolved characteristic of an organism that increases its fitness." Similarly, Wilson (1975:21) defines a trait as nonadaptive "if it reduces the fitness of individuals that consistently manifest it under environmental circumstances that are usual for the species." In both cases, the term "adaptation" is defined in terms of fitness. Bolin and Bolin state that I "obscure the distinction between adaptiveness and fitness." It is obvious that the blame is misplaced.

---

[1] Bolin and Bolin do not agree with Wilson's statement that the explanation of altruistic behavior is the central *theoretical* problem of sociobiology. Regardless of their personal opinion, there is no doubt that this unresolvable dilemma provided a major impetus in the historical development of sociobiology as a discipline (Quadagno, 1979:103).

[2] For a more detailed and comprehensible explanation of the theory as well as its criticisms, see Dawkins (1976:145–9).

So far, then, we can cull two statements from the sociobiological literature:

> (1) Any behavior pattern that increases fitness is adaptive; and
> (2) any behavior pattern that reduces fitness is nonadaptive.

These statements are not, in themselves, tautological. However, there is a third assumption—or, really, set of assumptions—made by sociobiologists, which make it possible to explain *any* given human behavior as the end product of natural selection. These assumptions are that existing traits of species are adaptive (Barash, 1977:33) and indicative of fitness (Wilson, 1975:67). Thus, Barash states, "A fundamental assumption of sociobiology is that behavior patterns are adaptive." In a similar vein, Daly and Wilson (1978:24) conclude that "species typical behavior is usually fit behavior." An example will illustrate the misuse to which these principles can be put.

In pursuing his case for the genetic basis of altruistic behavior, Trivers begins his explanation with the assumption that altruism between friends is an evolved characteristic. He states:

> The tendency to like others, not necessarily closely related, to form friendships and to act altruistically toward friends and toward those one likes will be selected for as the immediate emotional rewards motivating altruistic behavior and the formation of altruistic partnerships. (Trivers, 1978:213).

As evidence to support his hypothesis, Trivers cites research findings which demonstrated that altruistic behavior was correlated with friendship. Thus, he notes that "Sawyer (1966) has shown that all groups in experimental situations tested showed more altruistic behavior toward friends than toward neutral individuals. Likewise, Friedrichs (1960) has shown that attractiveness as a friend was most highly correlated among undergraduates with altruistic behavior" (Trivers, 1978:213). A few pages later, Trivers cites research which reaches the exact opposite conclusion. In this case, children were shown to behave more altruistically to a stranger than to a friend. Trivers (1978:219) states:

> Particularly toward strangers, humans may initially act more altruistically than toward friends. Wright (1942) has shown, for example, that third grade children are more likely to give a more valuable toy to a stranger than a friend.

This discrepancy, which might provide some persons cause for contemplation, poses no problem for Trivers. He is equally able to conclude that this behavior, too, is biologically based, the result of the forces of natural selection. As he explains:

> Selection will favor a mechanism for establishing reciprocal relationships. Since humans respond to acts of altruism with feelings of friendship that lead to reciprocity, one such mechanism might be the performing of altruistic acts toward strangers, in order to induce friendship. In short, do unto others as you would have them do unto you. (Trivers, 1978:219)

Once it is assumed that existing behaviors are either fit or adaptive or both, any human behavior can be explained genetically. Without using the apparently offensive term "adaptive fitness" which I admittedly (but inadvertently) coined, I am able to make the exact same argument as that made in my original essay. In the sociobiological explanation of human social behavior, the potential for tautological reasoning always exists.

Bolin and Bolin also argue that I treat fitness as denoting an ideal outcome, whereas sociobiologists view it as a process. There are two flaws in their argument. First, the definition of fitness which they accept as valid (Stent, 1978:213) refers to neither a process nor an outcome. Rather, it is simply a measure of reproductive success. Bolin and Bolin use the term "fitness" as both a kind of measure and a process, because they are coupling the standard definition of fitness with its sociobiological usage. They seem to forget that it is not the maximization of genetic fitness that is the process in evolutionary theory, but natural selection which in turn produces fitness.

Second, *I* do not equate the maximization of genetic fitness with an ideal end state (maximal phenotypic adaptiveness). This, unfortunately, is what sociobiologists sometimes do. As I stated, "Even though they [sociobiologists] are aware that evolution need not produce maximal solutions, they tend to forget or simply ignore the fact that this is the case" (Quadagno, 1979:105). The following quotation from Wilson (1975:156) illustrates this occasional tendency:

> When exploratory behavior leads one or a few animals to a breakthrough enhancing survival and reproduction, the capacity for that kind of exploratory behavior and the imitation of the successful act are favored by natural selection. The enabling portions of the anatomy, particularly the brain, will then be perfected by evolution.

Finally, Bolin and Bolin also state that I do not understand that fitness is relative to a given environment. I can only quote again from my paper, "the evolutionary process can only be defined and comprehended relative to a given set of environmental and demographic circumstances (Quadagno, 1979:105).

In my conclusion, I suggested that sociobiology is not applicable to the study of human social behavior. My statement was extreme as a matter of necessity. Few sociologists, including myself, would deny that there are biological limitations imposed on the range of possible social systems which can develop. However, the wildly speculative claims of some sociobiologists have only served to illustrate the dangers present when those claiming to be armed with the tools of "science" enter the realm of philosophy. The acceptance or rejection of sociobiology as a suitable approach to the study of human behavior ultimately lies in the future, a future which can be determined, in part, by how those who identify themselves as sociobiologists proceed. Sociobiologists, themselves—not their critics—have been their own worst enemy.

Weinberg and COLIN J. WILLIAMS are currently studying the determinants of black/white differences in sexual patterns. Williams is Associate Professor at Indiana University-Purdue University at Indianapolis, and a Senior Research Sociologist, Institute for Sex Research, Indiana University. His book, *American Sexual Standards*, written with Albert D. Klassen and Eugene E. Levitt, is forthcoming.

■ MARK ABRAHAMSON (Sudden Wealth, Gratification, and Attainment) is Professor and Department Head, Department of Sociology, University of Connecticut. To be published by Prentice-Hall in 1981 is his forthcoming book regarding classical theory and contemporary research. His continuing research is on patterns of dominance within and between metropolitan areas in the United States.

■ WILLIAM P. BRIDGES (Industry Marginality and Female Employment) is Assistant Professor, Department of Sociology, University of Illinois at Chicago. His current research involves developing a sociological conception of industry structure and identifying its relationships with the division of labor and the differentiation of the labor force.

■ FRANÇOIS NIELSEN (The Flemish Movement in Belgium after World War II) is Assistant Professor, Department of Sociology, University of Chicago. In addition to further research on the linguistic conflict in Belgium, he is interested in the mathematical and statistical aspects of dynamic models in sociology. He is preparing a survey of the high school student population of Hispanic origin, in connection with the "High School and Beyond" project at the National Opinion Research Center in Chicago.

■ DELBERT S. ELLIOTT (Reconciling Differences in Estimates of Delinquency) is Director of the Behavioral Research Institute as well as Professor, Department of Sociology, University of Colorado. He is the principal investigator of two studies: (1) "The Dynamics of Delinquent Behavior . . ." (funded by the Center for Studies in Crime and Delinquency, NIMH), which involves a national youth panel initially interviewed in 1977, with follow-up interviews annually through 1981; and (2) "The Dynamics of Delinquency and Drug Use," funded by the National Institute of Juvenile Justice and Delinquency Prevention, LEAA. His associate, and his co-author in this issue of ASR, is SUZANNE S. AGETON, a Senior Research Associate at the Behavioral Research Institute. She is the principal investigator on a study of sexual assault among adolescents, focusing on the question of vulnerability to such assaults as well as on the short- and long-term consequences of sexual assault. Her central involvement presently is as co-principal investigator on a national longitudinal study of delinquent behavior.

■ LOUISE SHELLEY (The Geography of Soviet Criminality), an Assistant Professor in the School of Justice, American University, Washington, D.C., is doing further research on the impact of development on crime, Soviet crime and criminology, crime in socialist countries, and corrections. She has edited *Readings in Comparative Criminology*, due for September, 1980, publication by Southern Illinois University Press which is also to publish her nearly completed book on development and crime in comparative perspective.

■ PAUL D. ALLISON (Analyzing Collapsed Contingency Tables) is Assistant Professor, Department of Sociology, Cornell University. With J. Scott Long, he is studying the effects of departmental prestige and resources on the research productivity of academic scientists. He is also developing new methods for analyzing event history data. His *Processes of Stratification in Science* is forthcoming from Arno Press.

■ ROBERT W. JACKMAN (Comment on Stack, ASR, December, 1978) is Associate Professor of Political Science, Michigan State University, East Lansing, Michigan. His current research involves: (1) Coups d'etat and related forms of political violence in Third World countries; and (2) the nature of social class identification in the United States.

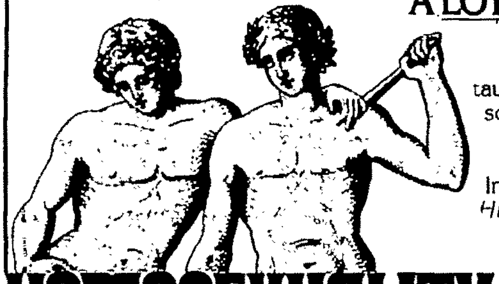
■ GLENN FIREBAUGH (Comment on Stack, ASR, December, 1978) is Assistant Professor, Department of Sociology, Vanderbilt University, Nashville. He is continuing his study of the linkages between agricultural change and population change in the Third World.

■ STEVEN STACK (Reply to Jackman and Firebaugh) is Assistant Professor, Department of Sociology, Indiana University. Currently he is working on cross-national studies of suicide. He also is investigating the relationship between unemployment rates and crime rates.

■ ROBERT BOLIN (Comment on Quadagno, ASR, February, 1979), Assistant Professor, Department of Sociology, North Dakota State University, is analyzing data on elderly victims of the Wichita Falls, Texas, tornado of 1979. His concern is to examine coping strategies and patterns of aid utilization among elderly families in environmental stress situations. SUSAN BOLTON BOLIN, his co-author, is a Ph.D. candidate, Department of Zoology, North Dakota State University, and is currently engaged in behavioral ecology research on flock behavior patterns and determinants of depredation among certain species of birds.

■ JILL S. QUADAGNO (Reply to Bolin and Bolin) is Assistant Professor of Sociology at the University of Kansas. She is doing an investigation of the social and economic conditions concerning poverty among the rural aged (in collaboration with Scott G. McNall). She has been in Cambridge, England, for several months, working with the Cambridge Group for the History of Population and Social Structure.

THE ANCIENT GREEKS DIDN'T GIVE
HOMOSEXUALITY A SECOND THOUGHT.
A LOT HAS CHANGED SINCE THEN.



Throughout history, homosexuals have been sent to prison, put in asylums, drugged, taunted, scorned, even executed. However, not all societies have been hostile toward homosexuals. The Greeks, for example, believed that homosexuality was a normal part of nature's plan. In his ground-breaking book, *Homosexuality: A History,* Vern L. Bullough outlines the forces that have led to our present-day attitudes toward homosexuality. He shows how social attitudes have a history, and how that history can tell us something about what we believe today. Comprehensive, far-reaching, and fair-minded, this book traces homosexual behavior from ancient Greece to the present.

HOMOSEXUALITY
A HISTORY
FROM ANCIENT GREECE TO GAY LIBERATION

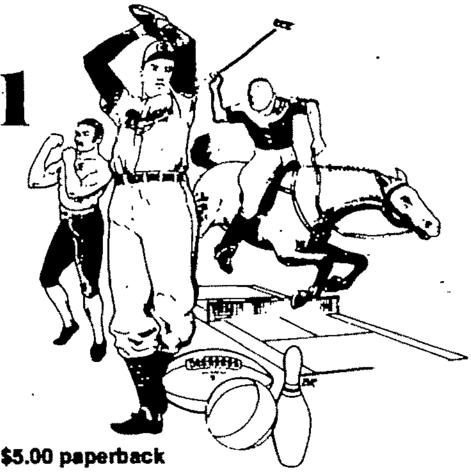
NAL

Now in paperback—". . . the most intelligent book yet published in English on modern sport." —*Journal of American History*

From Ritual to Record

The Nature of Modern Sports
ALLEN GUTTMANN



A deftly researched and highly entertaining profile of the nature of modern sports, *From Ritual to Record* is the most thorough look yet at the way our sports have developed to fill their special role in the contemporary world.

"Here is a study of popular culture as imaginatively serious as the best humanistic studies in literature and philosophy. And, special blessing, its style is graceful, demotic, witty."
—Patrick D. Hazard, *Annals*
"It is a pioneering work in a field remarkably little touched . . . required reading."
—Julian Symons, *Times Literary Supplement*

CAMBRIDGE

Portraits of "The Whiteman"

Linguistic play and cultural symbols among the Western Apache

Keith H. Basso

with a foreword by Dell Hymes

"Ethnographers are not the only ones who do ethnography and *Portraits of 'the Whiteman'* presents the most subtle evidence that this is so for North American Indians. It is absolutely at the cutting edge of developments in mutual understanding, to say nothing of the fact that it is superb anthropology."—*Alfonso Ortiz, University of New Mexico*

"Basso provides a rare insight into Western Apache perceptions of Anglo-Americans that should be required reading for anybody interested in native Americans."—*Library Journal*

Hardcover $14.95 Paper $4.95

Liberalism and Sociology

L. T. Hobhouse and Political Argument in England, 1880–1914

Stefan Collini

An historical account, based on extensive original research, of the relationship between Liberal political theory and the development of British sociology in the late 19th and early 20th centuries, especially as it was revealed in the work of Hobhouse.

Purdue University

Sociology:
AN INTRODUCTION,
SECOND EDITION

In direct response to user and reviewer comments, *Sociology: An Introduction, Second Edition,* more comprehensive than any other introductory sociology text on the market, has been updated and completely refined, and retains all the popular features of the successful first edition.

What you wanted refined:

- Eight new chapters by eight new authors providing better clarity, focus, and theoretical integration.
- Research methods chapter now appears as the last chapter of the book emphasizing its optional nature.
- Three chapters for the first edition covering social organization have been tightened and re-written by two new authors to focus on social interaction and social organization.

What you wanted retained:

Sociology: An Introduction, Second Edition still features the comprehensive, theoretically informed approach which caused the first edition to be adopted by more than 150 schools in its first year. The second edition also retains the popular running glossary, and biographical sketches of major theoreticians.

A Complete Ancillary Package to make teaching easier:

- An Instructor's Manual with film guide by Joseph Rogers, New Mexico State University.
- Study Guide by Joseph Rogers, New Mexico State University, with chapter summaries, outlines, key terms, concepts, phrases, names, self-tests, and suggestions for further study.
- Computerized test bank of 1,000 items to save instructor's time.

New for 1980

Understanding Human Sexuality

Joann S. DeLora
San Diego State University
Carol A. B. Warren
University of Southern California
Carol Rinkleib Ellison
Clinical Psychologist
About 432 pages • paper • Study Guide • Instructor's Manual • Forty 35mm slides • Just published

A concise, yet comprehensive overview of human sexuality from three perspectives — social, psychological, and medical-physiological — that encourages introspection and self-understanding. DeLora, Warren, and Ellison present a balanced, developmental picture of sexuality without becoming highly technical or theoretical.

Special extra: A *free* Study Guide comes shrinkwrapped with each *new* copy of the text.

Sociology of Education: An Introduction Second Edition

Sarane S. Boocock, Rutgers, The State University of New Jersey
About 448 pages • Just published

Can schools produce a high-level of cognitive learning without losing sight of other objectives? Can schools be instruments of social progress and reform? In the Second Edition, Boocock addresses these and other fundamental questions within a framework that helps students understand the relation of social factors and learning.

Sociology of Aging

Diana K. Harris
William E. Cole
both of University of Tennessee
About 480 pages • Instructor's Manual • Early 1980

Harris and Cole integrate aging within the framework of sociological principles. With comprehensive treatment, they examine social institutions (including education and religion), cultural values, socialization, the minority aged, problems of the elderly, and more. Reflecting the latest research, the text exposes many fallacies and "myth-conceptions" about the aged and aging.

Strangers to These Shores: Race and Ethnic Relations in the United States

Vincent N. Parrillo
William Paterson College
About 448 pages • Instructor's Manual • Early 1980

Parrillo's wide-ranging study of many groups helps students to gain insight into the patterns of majority-minority relations. He includes groups not usually covered, such as Vietnamese, Koreans, Arabs, Gypsies, Armenians, Greeks, and Poles. First-hand accounts by immigrants sharpen theoretical perspectives.

Issues in Feminism: A First Course in Women's Studies

Sheila Ruth
Southern Illinois University
About 704 pages • paper • Early 1980

From a feminist point of view, Ruth's text/reader presents a unified introduction to the diverse concepts and disciplines that make up Women's Studies. *Issues in Feminism* combines explication and analysis with abundant selections from sociology, anthropology, economics, law, literature, philosophy, and political science.

GRAMSCI AND MARXIST THEORY
EDITED BY CHANTAL MOUFFE *Visiting Lecturer,*
City University, London

This selection of essays by leading scholars provides an excellent and timely introduction to the work of Antonio Gramsci, focusing in particular on his advances in the study of the superstructures, and his relation to Marx and Lenin and his influence on Eurocommunism.

$24.50, *paperback* $12.95

ESSENTIAL INTERACTIONISM ***On the Intelligibility of Prejudice***
BARRY GLASSNER *Assistant Professor of Sociology,*
Syracuse University, New York

This book considers the purported instability of social science concepts by presenting a critique of causal and symbolic interactionist sociologies, and proposes in their stead a form of essentialism for sociology.

$21.00

PROBLEMS OF A SOCIOLOGY OF KNOWLEDGE
MAX SCHELER *Translated by Manfred S. Frings*

This work, which first appeared in 1924 and has never been published in an English translation, marks the first major investigation of its kind into the sociology of knowledge. In it Scheler challenges the social theories of Auguste Comte and Karl Marx, and expounds his belief that the sociology of knowledge is a major part of the sociology of culture and the foundation for all more specialized studies in the sociology and philosophy of religion, education, language and science.

International Library of Sociology $25.00

SOCIOLOGY OF YOUTH CULTURE AND YOUTH SUBCULTURES
MIKE BRAKE *Associate Professor of Social Work,*
Carleton University, Ottawa

Dr. Brake argues that subcultures arise as responses to collectively experienced problems resulting from defects and contradictions in the social structure. He discusses ethnic minorities and the problems facing them, femininity versus the *machisimo* identity, the emancipation of girls from the cult of romance and marriage, and the development of a new form of femininity.

$25.00, *paperback* $11.50

POLITICAL MANIPULATION AND ADMINISTRATIVE POWER

A Comparative Study

EVA ETZIONI-HALEVY ***Lecturer in Sociology, Australian National University***

Dr. Etzioni-Halevy examines the means by which elites in Western-style democracies have established and maintained themselves in power. She describes how they have manipulated the public by methods which run counter to the spirit and the letter of democracy without overtly disrupting the system. *International Library of Sociology* $22.50

VIOLENT CRIMINAL ACTS AND ACTORS

A Symbolic Interactionist Study

LONNIE H. ATHENS ***Professor of Sociology, Wayne State***

From the Foreword by Herbert Blumer: 'Dr Athens's study of the violent action of criminals is to the best of my knowledge the only such study that has been made from the standpoint of symbolic interactionism. It is truly a pioneering effort and a rewarding effort. Without any previous study to chart the way, he has had to carve out his own scheme of analysis ... it opens the door to a much-needed form of study in the grand task that confronts criminology.'

International Library of Sociology $11.50

INEQUALITY, CRIME AND PUBLIC POLICY

JOHN BRAITHWAITE ***Research Criminologist, Australian Institute of Criminology***

This study attempts to integrate and interpret the vast corpus of existing research evidence on social class, slums and crime. In so doing it provides the most comprehensive and systematic review available of the empirical evidence to support or refute the classic theories of Engels, Bonger, Merton, Cloward and Ohlin, Cohen, Miller, Shaw and McKay, as well as many more recent formulations. $32.50

OFFICIAL DISCOURSE *On Discourse Analysis, Government Publications, Ideology and the State*

FRANK BURTON ***Lecturer in Sociology, The City University, London;*** **and PAT CARLEN** ***Lecturer in Criminology, University of Keele***

This book is an unofficial report of theoretical investigations into a specific state practice — the publication of reports of official inquiries into law, order and justice issues.

International Library of Sociology $20.00

SOCIAL RESEARCH: Guides to a Decision-Making Process
By **Susan Gustavus Philliber,** Columbia University; **Mary R. Schwab,** University of Cincinnati; and **G. Sam Sloss,** Indiana University Southeast

This is an introductory text for a course in social research. It addresses the necessary steps in planning, conducting, evaluating, and presenting social research data. It covers the nature of knowledge and its application to social research; sources of research problems and influencing factors in their selections; understanding measurement issues; types of research design and factors to weigh in their use; techniques for collecting research data; understanding and utilizing data analysis; and ways to organize, summarize and present research findings.
February 1980 c. 200 pages c. $5.95 paper

THEORIES OF DEVIANCE, Second Edition
Edited by **Stuart H. Traub** and **Craig B. Little,** SUNY-Cortland

Theories of Deviance (revised edition) is a collection of seminal theoretical statements from diverse sociological perspectives. The flow of the book follows the development of the sociology of deviance from 19th century functionalism to contemporary explanations emphasizing political-economy. The book's aim is to provide students with an opportunity to recognize cross-fertilization, compatibility and contrast among the theorists whose work has been chosen. A brief introductory essay at the beginning of the book and introductions by the editors preceding each chapter help guide the students' reading. A *unique* feature of this edition is the inclusion of readings which analyze and critique each of the approaches to explaining deviance.
February 1980 c. 350 pages c. $8.95 paper

NEW TEXT WITH A SOLID "SOCIAL FACTS" APPROACH GIVES YOUR STUDENTS *TODAY'S* SOCIAL REALITIES

SOCIOLOGY: An Introduction

Michael S. Bassis, University of Rhode Island; **Richard J. Gelles,** University of Rhode Island; and **Ann Levine,** Professional Writer

This important new text gives in-depth coverage of basic topics for the introductory course. At the same time, its "social facts" orientation shows students, as in no other text, the *value* of the science and methodology of sociology in challenging myths and supporting reality. It does this through the innovative and fascinating device of first presenting commonly held *assumptions* (e.g., most only children are socially and intellectually backward; most murder victims are killed by strangers), then giving the often startling social *facts* as revealed by research findings (only children tend to have *higher* I.Q.'s and *stronger* self-concepts than those with siblings; most murder victims *know* their killers). These facts, in turn, are used as unforgettable illustrations of how social forces operate in all areas of human life.

SOCIOLOGY: *An Introduction* also features:

- sixteen-chapter division appropriate for a one-quarter as well as a full-semester course;
- real-life current examples and applications throughout, from comparisons between Vietnamese and American culture to the Jonestown tragedy as collective behavior;
- material on social change integrated into each chapter;
- thematic series of boxes—cross-cultural, subcultural, and historical—in each chapter;
- time lines placing each chapter's material in historical context;
- full graphics program of photos, charts, and graphs;
- Instructor's Manual and Student Study Guide.

WADSWORTH PUBLISHING COMPANY:
You Know Us by Our Authors

A textbook is only as good as its author. At Wadsworth we work with the best authors we can find, and these texts verify that we find the **best.**

New in 1980!

Sociology: An Introduction, Second Edition
Earl R. Babbie

One of the most readable and teachable texts of the 1970s takes a fresh and informative look at sociology in a New Second Edition. A broader research base with a 25% increase in references, a reorganization that explores Deviance after Socialization and distinguishes clearly between Organizational and Institutional Agreement, and new chapters on such topics as Groups, Formal Organizations, and Urban Society all add up to an insightful perspective for students.

There's **more**—boxes capsulize recent sociological studies, short stories by such noted authors as Kurt Vonnegut, Jr. dramatize sociological concepts, and a new design with numerous photographs and illustrations highlights key material. The list goes on and on, and we think you'll appreciate the new look this text gives to the 1980s. Teacher's Manual. Student Study Guide. Test Items.

Sociology: Concepts and Characteristics, Fourth Edition
Judson R. Landis

The best-selling **brief** introductory sociology text is now in a New Fourth Edition with provocative new readings, coverage of contemporary topics of concern, full page photographs, and a complete updating throughout. Teacher's Manual.

The Individual, Marriage, and the Family, Fourth Edition
Lloyd Saxton

Extensive updated research, a new art and photo presentation, and the same objective **facts** that made Saxton a household word. Teacher's Manual. Study Guide.

Social Psychology as Social Process
Donald E. Allen, Rebecca F. Guy, and Charles K. Edgley

The most current social psychology text that recognizes the contributions of sociologists to the field. An introduction from a symbolic interactionist perspective. Instructor's Manual.

Crime and Deviance in America: A Critical Approach
Sheila Balkan, Ronald J. Berger, and Janet Schmidt

Coverage of standard criminology topics within a pure, critical approach to the study of crime.

Social Research for Policy Decisions
Kurt Finsterbusch and Annabelle Bender Motz

Analyzes three major social research contributions to the policy decision process—social problem analysis, social impact assessment, and program evaluation.

New Viewpoints on Sociology, Psychology, and Social Work

INTRODUCING SOCIAL PSYCHOLOGY

EDWARD E. SAMPSON. Who Are You? Organized around this basic question, *Introducing Social Psychology* provides a unique and effective introduction to the major topics, theories, and research findings in social psychology. Six major areas are covered: culture and history; family; sex, sex roles, and sexism; attitudes, beliefs, and values; memberships, associations, and roles; personality and personal style. Here is a truly social view of the study of human behavior. Bibliography. Index.
February 1980, 288 pp.

Hardcover ISBN: 531-05413-6	$15.00
Paperback ISBN: 531-05627-9	$ 8.95

PSYCHOTHERAPY: Current Perspectives

THOMAS J. COTTLE and PHILLIP WHITTEN, Editors. The major issues, purposes, and forms of psychotherapy, plus some of the underlying philosophical principles, are clearly presented. Also discussed are various types of psychotherapy—from classical psychoanalytic to the more modern forms of group psychotherapy, sex therapy, bioenergetics, and family therapy. Finally, the book examines psychotherapy's own findings about human behavior. 305 pp.

Hardcover ISBN: 531-05411-X	$12.95
Paperback ISBN: 531-05625-2	$ 6.95

THE WORK OF SOCIAL WORK

ALLAN R. MENDELSOHN. Based on the first-hand experiences of a practitioner, educator, and consultant in the field, this study presents a no-nonsense, realistic picture of social work operations—their value base, knowledge base, and skill base.

What is social work? How does the actual practice differ from theoretical discussions of the occupation? This introductory textbook examines these important questions and will be of tremendous value to undergraduate and graduate students preparing to enter this profession. Index.
February 1980, 192 pp.

GOOD NEWS from Little, Brown

NEW for Social Problems

SOCIAL PROBLEMS
by Burton Wright and John P. Weiss. cloth/c. 610 pages/$15.95 tentative/ with Study Guide and Instructor's Manual

This new introductory text is based on the premise that in order to deal with social problems, we must first understand the social forces that cause and perpetuate them. The authors explore 15 social problems in 13 chapters and provide a unique and useful **integrating framework** for study. Each chapter includes an overview, an introduction, a historical overview, a conceptual orientation, the objective dimensions of the problem, attempts at dealing with the problem, and prospects for future solutions. SOCIAL PROBLEMS presents an orderly, objective approach to some knotty problems. Be sure to examine it soon.

NEW from John Irwin

PRISONS IN TURMOIL
by John Irwin. paper/c. 320 pages/$6.95 tentative

This fascinating account of how prisoners cope with prison life was written by one of this country's foremost authorities on prison. As a scholar and a former inmate, Irwin is uniquely able to translate his own experiences into an authoritative analysis of social change in the prison world. He explores the social structures that emerge in prisons, and analyzes them in their social and historical contexts. Controversial, provocative, and perceptive, PRISONS IN TURMOIL is the **ideal supplement** for a variety of courses.

All of these new titles are now available for examination.

NEWLY Revised for Marriage and Family

FAMILY IN TRANSITION: Rethinking Sexuality, Child Rearing, and Family Organization
Third Edition, by Arlene Skolnick and Jerome H. Skolnick. paper/c. 640 pages/$9.95 tentative/with Text Bank

In its new edition, the **most popular reader** for marriage and family courses continues to examine changes that have occurred in the family over the last decade, focusing on sexuality and sex roles, childhood and parenthood, the nature of the family, and social change. More than 70% of the material is new to this edition, including articles on love, coupling, divorce, divorce law, and remarriage.

NEW for the Sociology of Aging

SOCIAL GERONTOLOGY: An Introduction to the Dynamics of Aging
by David L. Decker. cloth/ c. 400 pages/$14.95 tentative/with Test Bank

Using a social and historical approach, this text explores the biological, economic, political, and psychological aspects of aging. A detailed analysis of the demographic shifts that have occurred within the last century provides a basis for examining the growing significance of aging as a social phenomenon. Social problems of the aged such as crime and victimization, medicare abuse, alcoholism, and suicide are treated in a separate chapter.

NEW for the Sociology of Health

THE SOCIOLOGY OF HEALTH: Principles, Professions, and Issues
by Fredric D. Wolinsky. cloth/c. 480 pages/$15.95 tentative

This comprehensive and readable examination of health-related behavior focuses on major principles, professions, and issues within the expanding field of medical sociology. In addition to discussing the social organization of health care, the author provides an in-depth analysis of the relationship between social factors and health.

CHARLES C THOMAS • PUBLISHER

GAMBLING TODAY

Edited by **David Lester,** *Richard Stockton State College, Pomona, New Jersey. (8 Contributors)* Gambling and gambling behavior are herein analyzed for their economic, sociological, criminological, psychological, and psychiatric ramifications.

The first three chapters of this timely book explore the potential impact of an increase in legal, as well as illegal, gambling. Specific topics include the social impact of the opening of the first casino in Atlantic City, the economic impact of casinos for communities interested in the tax revenues generated by legalized gambling, and the problems that legal and illegal gambling activities present for law enforcement officers.

The next three chapters present sociological motives for gambling and pertinent psychiatric and psychological theories. Among the questions addressed are *Why do people gamble? Is gambling disturbed or healthy behavior?* and *Can gambling be predicted on the basis of the payoff arranged by those who control the gambling establishments?*

Remaining chapters delineate treatment techniques for compulsive gamblers; the philosophy, experiences, and results of Gamblers Anonymous; and a cross-cultural analysis of gambling in Great Britain. *'79, 176 pp., 4 tables, $12.75*

OLD AND GROWING: Conversations, Letters, Observations, and Reflections on Growing Old *by* **Florence E. Vickery,** *College of Marin, Kentfield, California. Foreword by* **Jack Ossofsky.** Physical, psychological, and social aspects of the aging process are herein explained in everyday language and highlighted by glimpses into the lives of real people. Topics include retirement, changing roles in marriage and family, sexuality, loss of a spouse, bereavement and remarriage, loneliness, reengagement in new relationships, maintenance of health and well-being, and dealing creatively with death. *'78, 176 pp., 9 il., $13.00*

AN ECONOMIC ANALYSIS OF CRIME: Selected Readings *edited by* **Lawrence J. Kaplan** *and* **Dennis Kessler,** *both of City Univ. of New York, New York City. (25 Contributors)* This text discusses the activities and operations of organized crime, its economic implications, and its impact on the American consumer. Among the specific crimes examined are gambling, loansharking, narcotics, labor union corruption, crimes infiltrating legitimate business, pornography, and prostitution. *'76, 432 pp., 4 il., 9 tables, cloth-$22.25, paper-$16.50*

THE SEXUAL VICTIMOLOGY OF YOUTH *edited by* **LeRoy G. Schultz,** *West Virginia Univ., Morgantown, West Virginia. (21 Contributors)* The first section of this book considers the legal control of the sexual abuse of children. A short history of efforts in this field are presented along with discussions of the sexual victimization and molestation of children. Following sections cover medical and psychological diagnosis and treatment, incest, the victim and the justice system, the child sex industry, and sexual emancipation. The last of these constitutes a critical evaluation of age-of-consent and statutory rape laws. *'80, 456 pp., 1 il., 6 tables, $17.50*

THE EFFECTIVENESS OF SOCIAL CASEWORK *by* **Joel Fischer,** *Univ. of Hawaii, Honolulu. Foreword by* **H. J. Eysenck.** This work covers one of the most important topics in social work today—effectiveness of practice. The author, in the first part of this text, summarizes and analyzes all of the controlled research on casework effectiveness. In the following part, eleven leading social work theorists, researchers, educators, and practitioners respond to and critique the research analysis and discussion of Part I. *'76, 360 pp., 15 il., 7 tables, $25.00*

SOCIAL PSYCHOLOGICAL PERSPECTIVES ON AND RECREATION *edited by* **Seppo E. Iso-Ahola,** *Univ. of Iowa, Iowa City. (18 Contributors)* Contributors to this book review theoretical and empirical research and propose new directions for the leisure/recreation field. Practical implications of research findings receive special attention. The first of four sections deals with basic aspects, including theory and methodology. Succeeding sections cover the process of leisure socialization; the interdependent influences of social cognition, interaction, and leisure satisfaction; and the interdisciplinary nature of leisure studies. *'80, 448 pp., 6 il., 10 tables, $19.75*

PSYCHOTHERAPY FOR WOMEN: Treatment Toward Equality *edited by* **Edna I. Rawlings,** *Univ. of Cincinnati, Cincinnati, Ohio, and* **Dianne K. Carter,** *Univ. of Iowa, Iowa City. (22 Contributors)* A reflection of the feminist philosophy, this book provides alternatives to what the authors consider to be inadequate psychotherapeutic treatment of women today. They examine the feminist ideology and its relationship to such topics as assertion training, careers, therapy for lesbians, and social action. *'77, 500 pp. (6 3/4 x 9 3/4), 10 il., 16 tables, $22.25*

THE EVOLUTION AND CHEMISTRY OF AGGRESSION *by* **Delbert D. Thiessen,** *Univ. of Texas, Austin. Foreword by* **I. Newton Kugelmass.** The author of this book reviews the phylogenetic history of aggression and emphasizes its adaptive significance. Central to the book is the theme that human aggression is partially determined by genetic factors mediated through biochemical and morphological attributes. The effects of hormones and sex steroids on aggressive patterns are examined, as are brain biochemistry, the ways that pharmacological substances affect aggression, and the significance of chemosignals in directing aggression. *'76, 232 pp., 38 il., 27 tables, $23.75*

FAMILY VIOLENCE *by* **George Thorman,** *St. Edward's Univ., Austin, Texas.* Basic information is herein presented on the causes, treatment, and prevention of family violence. Initially, the author constructs a theoretical framework within which domestic violence can be understood. The nature and extent of child abuse and wife beating are reviewed, and statistical data and conclusions that can be drawn from them are given. Then, in separate segments on abused children and battered spouses, he focuses on aggressor and victim characteristics, including social/cultural factors and psychological profiles. A consideration of methods of treatment and prevention concludes the text. *'80, 208 pp., 1 table, $15.50*

DRUGS AND THE ELDERLY: Social and Pharmacological Issues *edited by* **David M. Petersen, Frank J. Whittington** *and* **Barbara P. Payne,** *all of Georgia State Univ., Atlanta. Foreword by* **Peter G. Bourne.** *(18 Contributors)* This text addresses such issues as drug side effects, drug interactions, self-medication, and community and institutional pharmacy. A final section emphasizes the responsibilities of the clinic and community with regard to drugs and the elderly and explores such related topics as physician and nurse responsibilities for educating the elderly about drugs, strategies for drug education, and social policy concerns and suggestions. *'79, 280 pp., 5 il., 9 tables, $26.25*

CONTEMPORARY SOCIAL GERONTOLOGY: Significant Developments in the Field of Aging *edited by* **Bill D. Bell,** *Univ. of Nebraska, Omaha. Foreword by* **Erdman Palmore.** *(61 Contributors)* The entire spectrum of gerontological concerns is herein covered, including the demography and ecology of age; theories of aging; economics, housing, and health; work, retirement, and leisure; and attitudes toward age and aging. Contributors also discuss adjustment and life satisfaction and the institutionalized aged. *'76, 480 pp. (6 3/4 x 9 3/4), 11 il., 99 tables, $36.25*

NEW FROM HARPER & ROW

In this long-awaited volume, noted British sociologist Tom Bottomore presents a wide-ranging examination of political sociology, or political science, from the viewpoints of competing schools of social theory. He confronts the different paradigms with each other and shows them in the context of an historical process that embraces not only the progress of the science itself, but also the transformation of its external environment as a result of economic, political, and cultural changes.

hardcover, $10.00
paperback CN751, $3.95

Political Sociology
Tom Bottomore

POWER IT'S FORMS, BASES, AND USES
DENNIS H. WRONG

Dennis Wrong offers a penetrating analysis of the elusive concept of power in social theory. He discusses a typology of diverse forms of power —authority, force, manipulation, etc.—then shows how the various forms blend and interact in real life. Exploring the concept of power, he shows how it can be used to examine the central issues of political sociology. In an important final chapter, he deals with power as a goal, and examines the roots in human nature of striving for power as a motive.

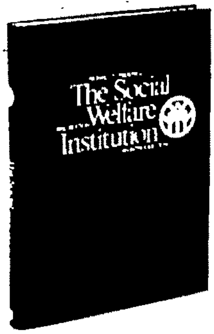
New Perspectives on Sociological Issues. . .

The Social Welfare Institution: An Introduction Third Edition



Ronald C. Federico
University of Cincinnati
1980/Casebound/416 pages

A basic introduction to social welfare institutions, this text combines both theoretical and practical issues. It retains the outstanding features of previous editions and adds new material such as a chapter on the helping process, a chapter on social work practice methods, a new appendix, and a new Instructor's Guide.

Delinquency: A Sociological View

Gary F. Jensen, University of Arizona
Dean G. Rojek, University of Georgia
1980/Casebound/352 pages

This text presents a systematic sociological analysis of juvenile delinquency with careful attention given to treatment and prevention. It examines the origins of adolescent misbehavior; appraises society's reaction to the problem; and discusses the success of the current system of juvenile justice in dealing with the problem.

Criminology: Perspectives on Crime and Criminality

Peter Wickman, State University of New York, Potsdam;
Phillip Whitten, and *Robert Levey*
1980/Casebound/640 pages

Written for the beginning student in criminology, the text covers major perspectives, issues, and the diverse concerns and debates that characterize contemporary criminology. The balanced "humanistic" view of criminology that is critical as well as current is designed to stimulate the student's systematic study of crime, criminality and criminal behavior.

Oxford University Press

Theoretical Criminology
Second Edition

GEORGE B. VOLD. Revised by **THOMAS J. BERNARD,** Guilford College. The standard work in its field now appears in a thoroughly revised second edition, expanded to include significant new developments in all major areas of criminological thinking. Retaining the style and historical framework of the first edition, Bernard incorporates the latest research in such disciplines as genetics, neurophysiology and learning theory in an intensive account of the major criminological theorists. New chapters discuss the anomie tradition, the ecology of crime, deviance and social reaction, and contemporary conflict and radical criminology. Annotated bibliographies follow each chapter.

November 1979 448 pp.; figures $14.95

Crime Control Strategies
An Introduction to the Study of Crime

HAROLD E. PEPINSKY, Indiana University. How can a knowledge of criminology be used to change the rates of crime and criminality, and what would the consequences of such change be? Pepinsky provides the first comprehensive introduction to the practical questions of crime control. Engagingly written, the text is designed to develop the reader's ability to critically analyze the issues of crime control in the context of society at large.

January 1980 384 pp. paper $9.95

Police Behavior
A Sociological Perspective

Edited by **RICHARD J. LUNDMAN,** Ohio State University. Research on police behavior has increased dramatically during the past fifteen years. This course-oriented anthology of eighteen articles samples recent studies on police decision-making, police-citizen interaction, police discretion, brutality and corruption. In his introductory commentaries on the readings, Lundman emphasizes the environmental and organizational roots of police conduct and misconduct.

January 1980 320 pp. paper $4.95

Women, Crime, and Justice

Edited by **SUSAN K. DATESMAN,** Arizona State University, and **FRANK R. SCARPITTI,** University of Delaware. The study of female crime has become one of the most popular topics in contemporary criminology. The fourteen articles collected here focus on the etiology of female crime, patterns of female criminal behavior, and the treatment of women in the criminal justice system. In addition, the editors have written a substantial introduction analyzing crime trends and the nature of female criminality, and a comprehensive concluding essay on the relation between women's crime and the women's movement.

January 1980 384 pp.; 19 tables paper $5.95

Suburban Youth in Cultural Crisis

RALPH W. LARKIN, Rutgers University. "A rare find—one that combines ethnographic sophistication with macro-social awareness. His book is not only relevant to education but to any student of socialization, social psychology or of American society." —Peter Freund, Montclair State College. "The best and most solid study of the tensions underlying the apparent but spurious resignation of American young people in the face of social and political insult."—Edgar Z. Friedenberg, Dalhousie University.

1979 272 pp. cloth $10.95 paper $4.95

Introductory Sociology

Order and Change in Society

Third Edition

GERALD R. LESLIE, University of Florida; **RICHARD F. LARSON,** Clemson University; and **BENJAMIN L. GORMAN,** University of Florida. *Introductory Sociology* is designed for students in the general survey course, majors and nonmajors alike. Stressing the interrelations of social life, social processes, and social institutions, the text thoroughly integrates major theoretical models and research methods. All the major substantive areas of contemporary sociology are covered. Clearly written in an engaging style, the text leads the student from basic terms and concepts to the analysis of complex social entities. Outlines at the beginning of each chapter, and summaries, lists of important terms, annotated readings, questions, and projects at the end of each chapter assist the student in assimilating the fundamental notions of the discipline. Lavishly illustrated and handsomely designed, broad-ranging yet closely reasoned, *Introductory Sociology* presents sound sociological principles in a manner both comprehensible and relevant.

January 1980 608 pp.; 200 photographs, 50 figures cloth $17.95

Complimentary Instructor's Manual

Socguide

An Aid to Learning Sociology through Projects, Puzzles and Problems to Accompany Leslie, Larson and Gorman: *Introductory Sociology*, Third Edition

MARGARET-MARY FRANZ, California State University. This student workbook provides readings, writing and research assignments, short answer questions, quizzes with answers, and brief essays focussing on basic concepts, terms and theories in each chapter of *Introductory Sociology*.

January 1980 160 pp.; 22 figures paper $4.95

A Primer on Ethnomethodology

KENNETH C.W. LEITER, Southern Methodist University. Ethnomethodology is an attempt to get beneath social behavior to find out how people understand the patterns of daily life. Drawing on the latest research, the *Primer* is a lucid description of the ethnomethodological perspective. Through the detailed analysis of numerous examples, Leiter clarifies the central concepts and concerns of ethnomethodology and demonstrates its relevance to contemporary sociology.

January 1980 272 pp. cloth $14.95 paper $4.95

The Environment

From Surplus to Scarcity

ALLAN SCHNAIBERG, Northwestern University. Schnaiberg provides a social scientific perspective on the institutional roots of the environmental crisis. Rejecting popular explanations of environmental deterioration, he concentrates on the prevailing influence of the unequal distribution of income, consumption, and economic and political power. An analysis of the generation and distribution of social surplus unifies this discussion of environmental problems, their roots in industrial production, and the obstacles to movements for environmental reform.

MARRIAGE, FAMILY, AND INTIMATE RELATIONSHIPS

Gary S. Belkin,
Long Island University
Norman Goodman,
State University of
New York at Stony Brook

A contemporary examination of the rich variety of marriage and family styles in American culture. The authors go beyond the typical whys and wherefores of "dating and mating" to consider the various social and psychological forces that shape the behavior of individuals in relationships. Their emphasis on communication and counseling as the means to the resolution of conflicts sets this book apart from others in the field. Its practical perspective allows students to apply the concepts and ideas to their own lives. Instructor's Manual.

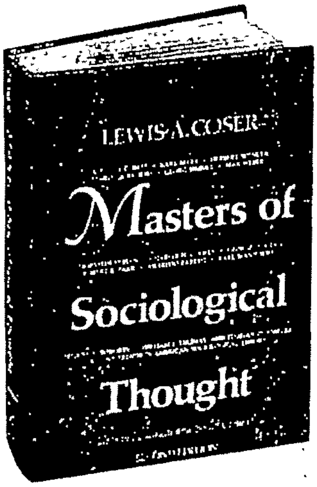
H J publishes th classics

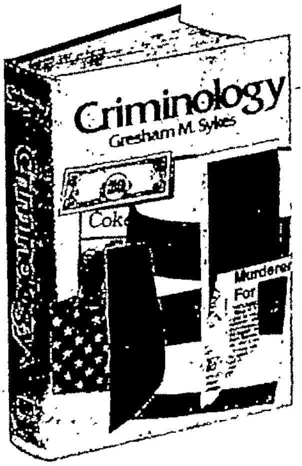
...the classic textbook on the evolution of sociological thought



Masters of Sociological Thought
Ideas in Historical and Social Context
SECOND EDITION
LEWIS A. COSER,
State University of New York, Stony Brook

A comprehensive presentation of sociological theory through in-depth study of the outstanding sociological theorists from the early 19th century to the present. "A superlative presentation, scholarly yet enjoyable to read."—Eric P. Godfrey, Ripon College

...the classic textbook on criminology



Criminology
GRESHAM M. SYKES, University of Virginia

A balanced introduction to criminology that provides broad coverage of the nature and causes of crime, the content of the criminal law, the workings of the criminal justice system, and society's various and changing reactions to crime and the criminal. "This is the most useful, balanced, and current text in criminology."—Roy Lotz, Washington State University

Central Problems in Social Theory

Action, Structure, and Contradiction in Social Analysis

Anthony Giddens

In this new and brilliantly original book of essays, Giddens discusses three main theoretical traditions in social science which cut across the division between Marxist and non-Marxist sociology: interpretive sociology, functionalism, and structuralism.

"One of the most creative among the younger generation of critical social theorists, Giddens stands alone in his concern for the classical tradition of sociology; but he also makes brilliant use of the latest philosophical and theoretical work of several contemporary schools and disciplines. A very important book for all of social science." —*Jeffrey C. Alexander*

$20.00 cloth, $8.95 paper

Poverty in the United Kingdom

A Survey of Household Resources and Standards of Living

Peter Townsend

The most detailed and comprehensive study of poverty ever undertaken for any society. It develops new measures, concepts, and methods which will be applicable to other settings and of direct comparative significance. It challenges many currently held ideas on the subject and will be an indispensable resource for policy makers as well as scholars.

$37.50 cloth, $15.95 paper

Catharsis in Healing, Ritual, and Drama

Thomas J. Scheff

What is catharsis? What are its effects and when does it occur? In this thoughtful and provocative study Scheff defines catharsis as a therapeutic process that discharges repressed emotions and is signalled by certain kinds of laughing, crying, and analogous responses reflecting discharge of fear and anger.

$12.95

The Fruited Plain

The Story of American Agriculture

Walter Ebeling

The drama and romance of American agriculture. Ebeling covers it all—from environmental problems to the effects of modern technology, from foreign land speculation to the back-to-the-land movement—in this exciting overview of agriculture in the U.S.A. He details the history and present status of agriculture for each of the seven geographic regions of the U.S.—from the Eastern seaboard to the Pacific Coast.

NOW AVAILABLE FOR THE CLASSROOM

THE SYMLOG CASE STUDY KIT

With Instructions for a Group Self Study

ROBERT F. BALES

The SYMLOG Kit provides a new and practical method for identifying group problems and solving them. This booklet clearly illustrates how a small group can observe and record its normal activities, and it contains all the forms necessary to undertake a group self study.

ISBN 0-02-910310-0 *$4.95*

WOMEN AND THE FUTURE

Changing Sex Roles in Modern America

JANET ZOLLINGER GIELE

"An interesting and useful effort to pull together much of the sociological literature on changing sex roles, to provide an interpretive framework in which these changes can be analyzed and understood, and to relate sex role changes to other important changes in modern industrial society."

—Anne Firor Scott, Duke University

ISBN 0-02-911690-2 *$6.95*

MARRIAGE AND FAMILY IN A CHANGING SOCIETY

Edited by JAMES M. HENSLIN

Unusually wide-ranging and contemporary in approach, this fresh and humane collection leads the student to a realistic understanding of marriage and the family today.

ISBN 0-02-914580-5 *$9.95*

THE MILITARY IN AMERICA

From the Colonial Era to the Present

Edited by PETER KARSTEN

Interweaving sociological and historical perspectives, the more than 40 articles in this book span 200 years of military history from colonial times to Vietnam and beyond. Critical issues affecting the military institution's image and role in contemporary society are examined in detail.

ISBN 0-02-916740-X *$9.95*

MANY SISTERS

Women in Cross-Cultural Perspective

Edited by CAROLYN J. MATTHIASSON

Written by and about women, this book movingly portrays the relationship of women to their society through 14 cross-cultural studies, revealing *what women do* and *how women feel.*

ISBN 0-02-920320-1 *$8.95*

READINGS IN MEDICAL SOCIOLOGY

Edited by DAVID MECHANIC

This rich assortment of 29 provocative readings introduces major issues and alternative perspectives on health, health care, and social policy.

ISBN 0-02-920700-2 *$9.95*

SOCIAL POLICY AND SOCIAL WELFARE

Structure and Applications

THOMAS M. MEENAGHAN &
ROBERT O. WASHINGTON

The authors create a general framework for analyzing social welfare policy, and demonstrate how this approach can be applied in specific areas of social service: social security, public welfare, community mental health, and programs for the elderly.

ISBN 0-02-920750-9 *$11.95*

THE SOCIOLOGY OF RACE RELATIONS

Reflection and Reform

Edited by THOMAS F. PETTIGREW

These readings chronicle the triumphs and failures of race relations in our nation, unfolding the tensions and struggles of racial conflict through the analyses of sociologists writing since the late nineteenth century.

ISBN 0-02-925110-9 *$9.95*

DETECTIVE WORK

A Study of Criminal Investigations

WILLIAM B. SANDERS

The first participant observation study of plain clothes detectives.
"The best writing about criminal investigation this reviewer has read ... a major contribution to the literature." —*Journal of Criminal Justice.*

The Calling of Sociology

and Other Essays on the Pursuit of Learning
Edward Shils

This third volume of the Selected Papers of Edward Shils brings together ten essays which deal with the history of American and European sociology as an intellectual undertaking and as a means to the attainment of practical ends. Professor Shils's main themes are the influence of ethical and practical intentions on scholarly study in the social sciences, the autonomy of the intellectual tradition of sociology, and the significance of the institutiona organization of sociological teaching and research.

Cloth 512 pages $25.00 February

Life Chances

Approaches to Social and Political Theory
Ralf Dahrendorf

Dahrendorf argues that the concept of life chances—the options that individuals in society face and the linkages which enable them to make their choices—should be a key concept for the understanding of social change.

Cloth 192 pages $15.00 Available

The Joyful Community

An Account of the Bruderhof—A Communal Movement Now in Its Third Generation
Benjamin Zablocki

"Although *The Joyful Community* is nominally about a religious cult, it is really an old fashioned community study—but one that is full of new insights, particularly on the relationships between community social structure and individual emotional structure. Ben Zablocki's book belongs on the shelves and reading lists of every social scientist concerned with communities and "community."—Herbert J. Gans, Columbia University

Paper 362 pages $3.95 February

W. E. B. Du Bois on Sociology and the Black Community

Edited and with an Introduction by Dan s. Green and Edwin D. Driver

With this volume, Dan Green and Edwin Driver make available to sociologists and other interested scholars a representative selection from Du Bois's most productive years as a sociologist (1896–1910), including many papers that are now out of print and difficult to obtain.

Paper 328 pages $5.50 February

The Black Extended Family

Elmer P. Martin and Joanne Mitchell Martin

The Martins point out that what appear to be fatherless, broken homes in our cities may really be vital parts of strong and flexible extended families based hundreds of miles away—usually in rural areas.

Paper 144 pages Illus. $3.95 February

The Gray Lobby

Henry J. Pratt

"*The Gray Lobby* is a success because it goes beyond the sphere of old age and provides an excellent model, based on the senior citizen movement, to explain the mass character of social movements in general, as well as policy systems and strategies for successful advocation and implementation of legislation."—Hedy Weinberg, *Social Service Review*

Paper 264 pages $5.95 February

The Self-Production of Society

Alain Touraine

Translated by Derek Coltman

In this rich, theoretical work, the distinguished French sociologist Alain Touraine states his conviction that society not only reproduces itself but also produces its own categories of functioning.

Paper 488 pages $7.50 February

The Organization of Interests

Incentives and the Internal Dynamics of Political Interest Groups

Terry M. Moe

"*The Organization of Interests* is an original and important book that will begin a new wave of studies connecting why people join groups to how they behave in them to what they accomplish."—Aaron Wildavsky

DORSEY 1980

INTERVIEWING: Strategy, Techniques, and Tactics,

Third Edition

Raymond L. Gorden, *Antioch College*

Presents basic concepts relevant to the interviewing process, richly illustrates them with concrete examples, and provides dozens of skill building activities in the form of critical questions, laboratory problems, and field problems.

EXPERIENCING SOCIAL RESEARCH,

Revised Edition (paperbound)

John F. Runcie, *Development Analysis Associates, Inc.*

A combination of text and carefully chosen problems stressing the learning of the more theoretical aspects of research methods and the application of what has been learned in the solving of problems.

THE URBAN ENVIRONMENT (paperbound)

Samuel E. Wallace, *University of Tennessee*

Integrates and synthesizes urban theory and research within the comprehensive perspective of ecology. Analyzes the historical past as it structures the present, the present as urbanites live it, and the future as seen in contemporary patterns.

INTRODUCTION TO SOCIAL WELFARE AND SOCIAL WORK: Structure, Function, and Process

Beulah R. Compton, *University of Minnesota*

Introduces students to the development of social welfare, the profession of social work, and the issues involved in the development of both the institution and the profession.

Examination copies for adoption consideration available on request. Please indicate course title and text presently used.

Fieldwork Experience

Qualitative Approaches to Social Research

edited by WILLIAM SHAFFIR, McMaster University, ROBERT A. STEBBINS, University of Calgary, and ALLAN TUROWETZ, Dawson College.

Through engaging first-person accounts, *Fieldwork Experience* introduces students to participant observation and unstructured interviewing as important social research methods. Twenty-one papers, all written especially for this volume, are organized according to the chronological sequence of field research: *Getting In, Learning the Ropes, Maintaining Relations,* and *Leaving the Field.* Together, they cover a wide range of research subjects, including drug-users, widows, delinquents, elites, pain sufferers, hustlers, artists, porno shops, gays, police, retardates, Moonies, and others. The editors provide introductions to each section and a comprehensive opening chapter.

Aging, the Individual and Society

Readings in Social Gerontology

edited by JILL QUADAGNO, University of Kansas.

With nearly forty selections spanning the field of social gerontology, integrated by substantial editorial essays, *Aging, the Individual and Society* combines the depth of a reader with the coherence of a text. Articles are organized in twelve sections: *Aging and Modernization; Theories of Aging; Stereotypes of Aging; Adult Socialization and the Life Cycle; Living Environments; Aging and Family Relationships; Work, Retirement, and Leisure; Minority Groups and the Aged; The Politics of Aging; The Economics of Aging; Health Care and Institutionalization; Death and Dying.* In introductions to each section Professor Quadagno reviews the relevant literature and discusses subjects beyond those covered in the papers themselves. Headnotes for each of the articles are provided as well.

CALCUTTA UNIVERSITY

Volume 45 April 1980 Number 2

Notice to Contributors

A processing fee of $10 is required for each paper submitted, except for comments; such fees will be waived for student members of ASA. A check or money order, made payable to the American Sociological Association, should accompany each submission. The fee must be paid in order for the review process to begin.

The length of an *ASR* paper is generally ten (10) printed pages or thirty (30) typed pages. However, the *ASR* is happy to accept manuscripts up to fifty (50) typed pages in length for review. We also are interested in receiving manuscripts for a Research and Notes Section.

To permit anonymity in the review of manuscripts, keep identifying material out of the manuscript. Attach a cover page giving authorship, institutional affiliation and acknowledgments, and provide only the title as identification on the manuscript and abstract.

ASA Multiple Submissions Policy: Submission of a manuscript to a professional journal clearly implies commitment to publish in that journal. The competition for journal space requires a great deal of time and effort on the part of editorial readers whose only compensation for this service is the opportunity to read papers prior to publication and the gratification associated with discharge of professional obligation. For these reasons, *the American Sociological Association regards submission of a manuscript to a professional journal while that paper is under review by another journal as unacceptable.*

SUBMISSION AND PREPARATION OF MANUSCRIPTS

1. Submit four (4) copies and retain the original for your files. Copies may be Xerox, mimeograph or multilith, but not carbons.
2. Enclose a stamped self-addressed postcard for acknowledgment of manuscript receipt. *Manuscripts will not be returned.* Please do not send your original copy.
3. All copy must be typed, doublespaced (including indented material, footnotes and references) on 8½ by 11 inch white opaque paper. Lines must not exceed six (6) inches. Margins must be a minimum of one inch.
4. Include four (4) copies of an abstract of no more than 150 words.
5. Type each table on a separate page. Insert a location note at the appropriate place in the text, e.g., "Table 2 about here." Send copies, retain originals.
6. Figures must be drawn in India ink on white paper. Send copies, retain originals.
7. Clarify all symbols with notes in the margins of the manuscript. Circle these and all other explanatory notes not intended for printing.
8. Footnotes should not be placed in the body of the text. Type them (doublespaced) and attach them as a separate appendix to the text. Number them consecutively throughout the text. Footnotes are to be kept to a minimum and used only for substantive observations. Source citations are made within the text rather than in footnotes.
9. Acknowledgments, credits and grant numbers are placed on the title page with an asterisk.

REFERENCE FORMAT

A. *In the text:* All source references are to be identified at the appropriate point in the text by the last name of the author, year of publication and pagination where needed. Identify subsequent citations of the same source in the same way as the first, not using *"ibid.," "op. cit.," or "loc. cit."* Examples follow:

1. If author's name is in the text, follow it with year in parentheses. [". . . Duncan (1959) . . ."]
2. If author's name is not in the text, insert, in parentheses, the last name and year, separated by a comma. [". . . (cf. Gouldner, 1963) . . ."]
3. Pagination (without "p." or "pp.") follows year of publication after a colon. [". . . Kuhn (1970:71)."]
4. Give both last names for dual authors; for more than two use "et al." in the text. When two authors have the same last name, use identifying initials in the text. For institutional authorship, supply minimum identification from the beginning of the complete citation. [". . . (U.S. Bureau of the Census, 1963:117) . . ."]
5. Separate a series of references with semicolons and enclose them within a single pair of parentheses. [". . . (Burgess, 1968; Marwell et al., 1971; Cohen, 1962) . . ."]

B. *In the appendix:* List all source citations by author, and within author by year of publication, in an appendix titled "References." The reference appendix must be complete and include all references in the text. The use of "et al." is not acceptable in the appendix; list the names of all authors. (See A. 4. for text format.)

If there is more than one reference to the same author and year, distinguish them by the letters, a, b, etc. added to the year. [". . . Levy (1965a:331) . . ."] Give the publisher's name in as brief a form as is fully intelligible. For example, John A. Wiley and Sons should be "Wiley." If the cited material is unpublished, use "forthcoming" with name of journal or publisher; otherwise use "unpublished."

Use no underlining, italics or abbreviations.

Examples follow:

1. *Books:* Jud, Gerald J., Edgar W. Mills, Jr. and Genevieve Walters Burch
   1970 Ex-Pastors. Philadelphia: Pilgrim Press.
   U.S. Bureau of the Census
   1960 Characteristics of Population. Volume 1. Washington, D.C.: U.S. Government Printing Office.
   Bernard, Claude
   [1865] 1957 An Introduction to the Study of Experimental Medicine. Tr. Henry Copley Greene, New York: Dover.
2. *Periodicals:* Conger, Rand
   Forthcoming "The effects of positive feedback on direction and amount of verbalization in a social setting." Pacific Sociological Review.
   Merton, Robert K.
   1963a "The ambivalence of scientists." Bulletin of The Johns Hopkins Hospital 112:77–97.
   1963b "Resistance to the systematic study of multiple discoveries in science." European Journal of Sociology 4:237–82.
3. *Collections:* Davie, M.
   1938 "The pattern of urban growth." Pp. 133–61 in G. Murdock (ed.), Studies in the Science of Society. New Haven: Yale University Press.

See recent issues for further examples.

SCOPE AND MISSION OF AMERICAN SOCIOLOGICAL REVIEW: The *American Sociological Review* publishes work of interest to the discipline in general, new theoretical developments, results of research that advance our understanding of the most fundamental social processes, and important methodological innovations. Like other publications of the Association, emphasis is given to exceptional quality. Unlike the more specialized journals of the Association, the *American Sociological Review's* primary focus is on whatever has the most general bearing on the knowledge of society.

Concerning manuscripts, address: Editor, *American Sociological Review*, Department of Sociology, University of Illinois, Urbana, Illinois 61801. (217) 333-6515.

The *American Sociological Review* (ISSN 0003–1224) is published at 49 Sheridan Avenue Albany, New York, bimonthly in February, April, June, August, October, and December.

Applications for permission to quote from this journal should be addressed to the Executive Office

Copyright © 1980 American Sociological Association.

Annual membership dues of the American Sociological Association, $20–$120 ($10 of this amount may cover a subscription to the *American Sociological Review*); Associate, $25; International Associate, $25; Student Associate, $12.

Application for membership and payment of dues should be made to the Executive Office. Subscription rate for members, $10; nonmembers, $15; institutions and libraries, $30; nonmember students, $10. Single issue, $4.

New subscriptions and renewals will be entered on a calendar year basis only.

Change of address: Six weeks advance notice to the Executive Office and old address as well as new are necessary for change of subscriber's address.

AMERICAN SOCIOLOGICAL REVIEW

FERTILITY AND FEMALE EMPLOYMENT: PROBLEMS OF CAUSAL DIRECTION*

JAMES C. CRAMER
University of California at Davis

American Sociological Review 1980, Vol. 45 (April):167–190

Seemingly contradictory results have been reported recently on the causal relationship between fertility and female employment. Data from the Panel Study of Income Dynamics are used to investigate four possible explanations of the contradictions: (1) multicollinearity in nonrecursive models; (2) misspecification of models; (3) discrepancies between attitudes or intentions and behavior; and (4) differences between static and dynamic models. All four explanations are pertinent to the controversy. It is found that the dominant effects are from fertility to employment in the short run and from employment to fertility in the long run. Multicollinearity often is a serious problem in nonrecursive models. Dynamic models are much more informative than static models. Plans generally seem to be consequences more than determinants of behavior. Results (sometimes) depend upon how variables are measured, upon what time intervals are used, and upon aggregate trends and cycles and historical circumstances. Other substantive findings and general methodological issues are discussed briefly.

Many of the major controversies in the study of fertility involve questions of causal direction. At the macrotheoretical level it has been debated—at least since Malthus—whether economic well-being determines fertility or fertility determines well-being. In recent decades, "economic development" has been the popular name for well-being and, currently, income distribution is becoming a new focus for the same debate (Lindert, 1978). At the microlevel of households, related controversies are more complex because household income can come from different sources; so theories must consider sex roles as well as fertility and level of income. Among the many issues here, the most important problem is the relationship between fertility and female employment.[1] Many studies indicate that a wife's childrearing responsibilities constrain her labor force activity (Bowen and Finegan, 1969; Sweet, 1973). On the other hand, wife's labor force activity or plans often are found to be good predictors of her expected fertility (Bumpass and Westoff, 1970; Ryder and Westoff, 1971; Whelpton et al., 1966).

Rather than debate which causal interpretation of female employment and fertility is correct, demographers have been inclined to believe that both are correct (Bagozzi and Van Loo, 1978; Easterlin, 1978; Hawthorn, 1970; Turchi, 1975b; Willis, 1973). This approach to the problem of causal direction has been stimulated greatly by an increasing awareness of the development, originally in macroeconomics, of statistical models for estimating reciprocal causal relationships. The problem of causal direction is common in other areas of sociology besides fertility, and the use of models of reciprocal causality is increasing rapidly (Land and Felson, 1978). In the various demographic and sociological applications one senses a tempting hope that such nonrecursive models can answer questions of causal direction simply and empirically—just specify both directions,

The research for this paper was supported by NICHD grant 5-RO1-HD10233-02. The author gratefully acknowledges computing assistance from Bernadette Tarallo and helpful suggestions from John Czajka, Thomas Dietz, Maurice MacDonald, and the anonymous referees.

[1] The ambiguity of causal direction is evident also in policy proposals. Smith (1972) recommends reducing poverty by lowering fertility, while Stolzenberg and Waite (1977) discuss the possibilities of lowering fertility by raising female earnings.

and see which is stronger. But the hope of such a simple solution is naive.

Some of the difficulties encountered in empirical research using nonrecursive models can be detected from a comparison of two recent studies, by sociologists, of the relationship between fertility and wife's employment. Both studies were stimulated by the developing economic theories of household decision-making as well as by social-psychological research on female employment, sex roles, and fertility. Both studies used large national samples of relatively young married couples, and the samples were interviewed at roughly the same date (1970 and 1973)—yet the two studies obtained seemingly opposite results. Waite and Stolzenberg (1976; Stolzenberg and Waite, 1977) examined the relationship between expected family size and wife's expected employment status at age 35.[2] They found a strong effect of employment plans on expected fertility and only a very weak effect in the opposite direction. Smith-Lovin and Tickamyer (1978) studied the number of years worked by the wife since marriage and the number of live births during the same time period. They found a strong effect of fertility on years employed and only a very weak effect in the opposite direction.

There are a number of possible explanations for the difference in results. (1) The difference may be due to technical problems in estimating the nonrecursive models, particularly multicollinearity (Turchi, 1975a:88). (2) The models could be misspecified. As Land and Felson (1978) note, most sociological nonrecursive models are arbitrarily identified according to availability of data. The two models of fertility and wife's employment use different instrumental variables and define some variables in controversial ways. (3) One of the models deals with expectations (attitudes), while the other deals with reported behavior; consistent results may not be reasonable if fertility and employment attitudes and behavior are only weakly associated (due perhaps to biological or labor market contingencies). (4) Finally, one of the models is static, while the other ostensibly is dynamic. The relationship between causal processes and outcomes is extremely subtle and complex (Carlsson, 1972). It may be that the two models can be reconciled and shown not to be inconsistent after all.

The primary purpose of this paper is to explore the causal relationship between fertility and wife's employment using the studies by Waite and Stolzenberg and by Smith-Lovin and Tickamyer as a point of departure. Other nonrecursive demographic models have been estimated, but these two studies illustrate quite nicely most of the important issues. These issues—multicollinearity, model specification, attitudes (plans, anticipations) and behavior, and static and dynamic models—confront all sociological models of reciprocal causal relationships, yet they are seldom discussed adequately. A second, and not unimportant, purpose of this paper is to illustrate these general issues during the exploration of the fertility-female employment relationship.

The organization of the paper is as follows. The problem of multicollinearity is defined in the first section, and its symptoms are identified in the studies by Waite and Stolzenberg and by Smith-Lovin and Tickamyer. These two studies are replicated as closely as possible in the second section and evaluated by a sensitivity analysis; this section serves also as an introduction to a relatively complicated data set. In the third section, several specification problems are discussed, such as the measurement of economic variables and time intervals in dynamic models, and a dynamic model of fertility and employment behavior is estimated. Additional specification problems are discussed in the following section (for example, distinguishing between if and when events occur in dynamic models), and a dynamic model incorporating both employment and fertility intentions and behavior is estimated. In the final section the substantive and methodological results are summarized and evaluated.

The data analyzed here are from the Panel Study of Income Dynamics, a large national sample of households interviewed in 1968 and reinterviewed annually (Duncan and Morgan, 1976). Members of 1968 families who subsequently split and formed new households were followed and interviewed each year after splitting off, so cross-sectional samples remain nationally representative and do not necessarily become progressively older (that is, there are about as many young respondents in 1976 as in 1968).[3] Many questions were asked every year and can be used for longitudinal analyses of stable families. Some questions were asked only in certain years and so can be analyzed only for subsamples of families in existence in those years. An important case of unique questions occurred in 1976, when wives also were interviewed in addition to the usual annual interview with husbands or unmarried heads of households. All analyses reported here are based on samples of young married couples. Beyond this pervasive characteristic, the models use different questions and different subsamples of families; specific details are discussed for each new model.

---

[2] Waite and Stolzenberg report results both for currently married and single women, but only the results for married women are discussed here.

THE PROBLEM OF MULTICOLLINEARITY

The general structure of nonrecursive models and the problems of identification and estimation have been presented quite clearly by Blalock (1969), Duncan (1975), Goldberger (1973), and others, and the reader is assumed to have some familiarity with this material. Our first concern, in analyzing nonrecursive models of fertility and wife's employment, is the problem of multicollinearity, which often is alluded to in the technical literature but seldom is discussed directly or in accessible jargon (Duncan, 1975: 86–90; Fisher, 1971; Johnston, 1972:280–1, 393, 410–12; Rao and Miller, 1971: 216–20). Relatively simple nonrecursive models usually are estimated by two-stage least squares (2SLS), an estimator often characterized as "consistent but inefficient." The inefficiency of 2SLS is most acute with cross-sectional survey data (Rao and Miller, 1971:220) and, thus, is more likely to be a problem for sociologists than is indicated in the econometrically oriented technical literature. One of the less-often noted sources of inefficiency is multicollinearity. This problem, which on casual inspection of the empirical literature seems to be common,[4] can be described by a simple hypothetical example.

In a nonrecursive model with two endogenous variables (x_1 and x_2), each with one instrumental variable (x_3 and x_4 respectively) and a joint exogenous predictor x_5 (where all variables are measured without error as deviations from their means), the equation for x_1 is estimated by 2SLS as

$$x_1 = b_{12}\,\hat{x}_2 + b_{13}\,x_3 + b_{15}\,x_5 + U$$

where $\hat{x}_2$ is the predicted value of x_2 obtained from the regression of x_2 on all predetermined variables x_3, x_4, and x_5 (the first-stage regression). If x_4 is a weak instrument for x_2, then $\hat{x}_2$ will be nearly a perfect linear combination of x_3 and x_5 and multicollinearity will be a potentially serious problem in the x_1 equation. x_4 is "weak" either if x_2 and x_4 are relatively weakly correlated or if x_4 is highly correlated with x_3 or x_5. A useful measure of the weakness of x_4 as an instrument is the coefficient of determination (R^2) from regressing $\hat{x}_2$ on the other predictors of x_1 (that is, x_3 and x_5); a coefficient near 1.0 indicates high multicollinearity. This specialized use of R^2, equivalent to a measure proposed recently by Chatterjee and Price (1977), will be denoted M^2.

---

[3] In estimating the regression models, weights are used to adjust the data for disproportionate stratified sampling, differential response rates, and split-offs. The design effects of the clustered sampling and weighting are not known, so estimates of standard errors are only approximate. These estimates are not presented with the regression results, and questions of statistical significance are treated cautiously and conservatively.

[4] The same problem of multicollinearity can arise in recursive models if one of the independent variables is constructed from a prediction equation involving the other independent variables. This occurs often in fertility models because of the assumed importance of future (expected or permanent) income. For example, Rosenzweig and Seiver (1975) construct a measure of permanent income using husband's education, age, and occupation and then use both permanent income and husband's education to predict fertility. Their results suggest possible problems of multicollinearity: large standard errors and implausible coefficients for the two variables.

The major consequence of multicollinearity is that estimates of the regression coefficients are unreliable. The standard error of b_{12} is inversely proportional to $(1-M^2)$; with high multicollinearity this quantity is close to zero, so the standard error is large. The standard errors of the other coefficients (b_{13} and b_{15}) are not independent, and they, too, are large to the extent that x_3 and x_5 are correlated with $\hat{x}_2$.[5] In any particular sample there is a substantial risk that the estimates of b_{12} and other slopes are quite far from the "truth." The slopes of the reciprocally causal variables, in particular, may be implausibly large or have the "wrong" signs. Slopes of endogenous variables with surprising magnitudes and signs are found in the two nonrecursive models of female employment and fertility described earlier. These are symptoms that multicollinearity may be serious, although definite judgments are impossible because of insufficient published information. The evidence for high multicollinearity will be described briefly, and its possible consequences are explored in the next section.

Waite and Stolzenberg (1976) estimate a model of expected family size (EFS) and of whether the woman expects to be employed at age 35 (LFPP), for a sample of women under age 30; separate (but similar) estimates are reported for married and unmarried women. Each endogenous variable has two instruments and, in addition, wife's age, education, race, and husband's income (in the "married" sample) are specified as joint predictors. The instrumental variables predicting expected family size are ideal family size and wife's number of siblings. The latter variable is irrelevant in their models, but ideal family size is very strongly associated with EFS. Using 2SLS, EFS is estimated to have only a very weak effect on LFPP.

The instrumental variables predicting employment plans are the labor force activity of the woman's mother and an index of attitudes regarding working mothers. Both instruments are only weakly related to LFPP, but so are the joint predictors. The importance of ideal family size in the first-stage regression cannot readily be ascertained from the published information, but it seems likely that it is a moderately strong predictor and that the instruments for LFPP may be relatively weak (that is, M^2 may be large). The results are symptomatic of multicollinearity: using 2SLS (but not OLS), LFPP is estimated to have a very large effect on EFS. The authors themselves express surprise at the results, although they do not include multicollinearity among their post-hoc explanations.

In our second case study, Smith-Lovin and Tickamyer (1978) estimate a model of number of children ever born (presumably since marriage) and number of years employed, since marriage, for a sample of once-married wives at age 30. Each endogenous variable has several instruments, and there are a number of joint predictors of which only wife's education, husband's income, and marital duration are at all important. The instrumental variables predicting family size are indexes of religious affiliation and commitment, sterility, and number of siblings. The latter variable is irrelevant but the other instruments appear to be acceptably strong, although marital duration (a joint predictor) clearly is the main determinant of number of children ever born. Using 2SLS, family size is estimated to have a quite strong effect on wife's years employed.

The instrumental variables predicting wife's employment since marriage are her employment experience before marriage and her mother's employment status. The latter variable seems to be unrelated to wife's employment and fertility and is irrelevant as an instrument. Premarital employment experience is significant—but almost certainly (the relevant information is not reported), it is nearly collinear with other predictors and, thus, is probably a weak instrument. The sample is an age cohort, so marital duration also identifies age at marriage. "Years worked before marriage" is defined to exclude part-time work while in school, and most women in the sample completed schooling before marriage, so years of schooling and years employed before marriage must nearly define age at marriage. The problem of high multicollinearity among these three variables is particularly serious because age at marriage/marital duration is a very strong predictor of both employment and fertility. Perhaps the multicollinearity associated with the weakness of premarital employment as an instrument explains the unexpected result that wife's employment is estimated to have a very small, but positive, effect on fertility.

---

[5] The interdependencies among standard errors are described mathematically by Johnston (1972:160–3). Other problems associated with 2SLS besides multicollinearity are discussed by Fox (1978), Hout (1977), and Luskin (1978).

Despite the evidence of weak instruments in these two studies, it cannot be shown that the results are distorted by multicollinearity. Multicollinearity simply leads to unreliable estimates; in any particular sample, the estimates may be either accurate or highly misleading. One possible response to this uncertainty is to eschew 2SLS, but simulation studies suggest that OLS and alternative estimators often are worse evils (Atkinson, 1978; Johnston, 1972; Rao and Miller, 1971). A second response is to compare estimates from different samples. Waite and Stolzenberg's results are supported by Cain and Dooley (1976), who found a large effect of female employment on fertility (and a negligible reciprocal effect) from aggregated 1970 census data; and by Butz and Ward (1977) in an aggregate time series analysis. Smith-Lovin and Tickamyer's results also have been supported in different models using the same data (Cain, 1979) and using other data (Cramer, 1979a; Hout, 1978). The supporting evidence is inconclusive, however, because many of these studies also show indications of problems with multicollinearity. A third response is to perform sensitivity analyses using alternative sets of instrumental variables (Land and Felson, 1978). This approach will be taken with Income Dynamics data.

SENSITIVITY ANALYSIS OF MULTICOLLINEARITY

Sensitivity analyses may be designed as experiments in which the alternative sets of instrumental variables represent a range of degrees of multicollinearity. Such an experiment is not conclusive, but it may provide evidence on the stability of results. The drawback, of course, is theoretical impurity: causal models are supposed to be theoretically derived and meaningful, not arbitrarily specified experiments. Probably it is premature to worry about this drawback, as most sociologists seem to work in a theory-construction mode. As Land and Felson note (1978), much research employs large data sets (often collected for other purposes) with many variables and weak theories that are relatively permissive regarding specification of exogenous variables. The two studies examined above conform to this description: both are secondary analyses of multipurpose data sets and are somewhat arbitrarily specified.[6]

Employment and Fertility Plans

Questions about expected family size and wife's employment plans were asked in 1972, but Waite and Stolzenberg's model cannot be replicated exactly. Expected family size is reported by the husband, and, for our purposes, we must assume (as is common in microeconomic models) that husbands and wives have identical preferences. Husbands reported wives' labor force plans "in the next few years," rather than "at age 35"; and there are no data on wives' employment attitudes or mothers' employment. Other variables in their model are available but, sometimes, only from interviews taken before 1972. Alternative models are estimated, using weak and strong instruments for both labor force plans (LFP) and expected family size (EFS). The instrumental variables for EFS are ideal family size (strong) and religion and number of siblings (weak). The instruments for LFP, in place of work attitudes, are wife's prior work experience[7] (whether employed at any time, 1967–1969, a strong instru-

---

[6] That is, the selection of variables is influenced by theories and is plausibly justified, but it is not derived from theory; it is also heavily influenced by what variables happen to be available in the data sets.

[7] The assumption here is that work experience is strongly indicative of employment attitudes and tastes; Heckman and Willis (1977), among others, provide evidence on this. Hout (1978) also uses work experience as an instrumental variable (for current employment, not employment plans).

Table 1. Standardized Regression Coefficients from Three Nonrecursive Models of Wife's Labor Force Plans (LFP) and Expected Family Size (EFS) in 1972

	LFP As Dependent Variable			EFS As Dependent Variable		
	1	2	3	1	2	3
LFP[a]				−.26	−.29	−.24
EFS[a]	−.17	.77	−.10			
Prior employment	[b]	.47	.37	[b]	[c]	[c]
Youngest child 0–2	−.07	[b]	[b]	[c]	[b]	[b]
Wife's age	.06	−.17	.10	.28	.32	.28
Wife's education	.13	.26	.09	−.12	−.13	−.12
Race	.06	−.09	.02	.11	.13	.11
Husband's income	−.23	−.09	−.16	−.13	−.13	−.13
Ideal family size	[c]	[b]	[c]	.26	[b]	.26
Catholic	[b]	[c]	[b]	[b]	.06	[b]
Number of siblings	[b]	[c]	[b]	[b]	.11	[b]
M^2 of endogenous predictor's instruments	.71	.95	.72	.92	.32	.32
R^2 from first-stage regression	.07	.20	.20	.24	.19	.24

[a] The standardized coefficients for the endogenous predictors are estimated by a two-step process using Hout's recommended formula (Hout, 1977).

[b] Variable excluded from this model.

[c] Variable excluded from this equation but included in model.

ment) and age of youngest child in 1972 (whether under age three, a weak instrument). Wife's age, education, race (whether black), and husband's earnings are joint predictors. The sample is restricted to couples stably married 1968–1972, wife under age 37 in 1972, and either no children in 1972 or youngest child under age eight (N = 639).[8]

Results for three models are presented in Table 1. Models 1 and 2 each feature a strong instrument for one of the endogenous variables and a weak instrument for the other. In model 3 both endogenous variables have strong instruments. All the LFP equations exhibit fairly high multicollinearity, although ideal family size is a somewhat stronger instrument for EFS (M^2 under .75) than are religion and number of siblings, together (M^2 = .95). The estimated effects of EFS and the joint predictors seem to be sensitive to the small differences in multicollinearity, with highly implausible estimates in the model with weak instruments. In the better models, expected family size seems to depress labor force plans by a small amount. There is much greater variation in the multicollinearity present in the EFS equations, as prior employment is a much stronger instrument for LFP than is age of youngest child. In spite of this, all estimates are similar in the three models: employment plans depress expected family size by a moderate amount. Thus, multicollinearity is a potential danger in these models, but its effects are unpredictable. Employment plans clearly seem to have an effect on expected family size, but there appears to be a reciprocal effect, also, and the latter is not clearly smaller than the former.[9]

Expected family size and employment plans were also asked about, in the 1976 interviews of wives, permitting an alternative sensitivity analysis of Waite and Stolzenberg's model. The instrumental variables for EFS and the joint predictors are the same as before. Prior employment (whether employed at any time, 1971–1973) and age of youngest child (whether under age of three in 1976) are, again, instruments for LFP. An additional instrument for LFP is whether the wife was ever

---

[8] Wife's age is restricted so that, on average, labor force plans "in the next few years" refer to age 35. Other departures from Waite and Stolzenberg's sample criteria are due to data limitations or to constraints imposed by other uses of these data in later sections.

[9] That is, the difference between estimated coefficients probably is not statistically significant (this cannot be estimated reliably with these data and the available computer software). Effects of other variables in the models generally are in expected directions with plausible magnitudes. Similar results are obtained with EFS dichotomized as under three children or three or more (that is, scaled 0–1, the same as LFP).

Table 2. Standardized Regression Coefficients from Three Nonrecursive Models of Wife's Labor Force Plans (LFP) and Expected Family Size (EFS) in 1976

	LFP As Dependent Variable			EFS As Dependent Variable		
	1	2	3	1	2	3
LFP				−.29	−.22	−.19
EFS	.85	.02	.18			
Prior employment	.27	.14	[a]	[b]	[b]	[a]
Husband's approval	.52	.46	.50	[b]	[b]	[b]
Employed before marriage	[a]	[a]	.04	[a]	[a]	[b]
Youngest child age 0–2	[a]	[a]	−.06	[a]	[a]	[b]
Wife's age	−.26	−.09	−.15	.16	.17	.15
Race	−.08	.02	.01	.11	.12	.10
Wife's education	.20	.06	.11	−.12	−.14	−.11
Husband's earnings	−.07	−.03	−.09	.04	.08	.08
Ideal family size	[a]	[b]	[b]	[a]	.26	.26
Catholic	[b]	[a]	[b]	.10	[a]	.08
Number of siblings	[b]	[a]	[b]	.11	[a]	.10
M^2 of endogenous predictor's instruments	.91	.67	.71	.27	.23	.30
R^2 from first-stage regression	.32	.30	.30	.15	.21	.23

[a] Variable excluded from this model.

[b] Variable excluded from this equation but included in model.

employed before marriage. Also, in 1976, wives were asked,

> "How does your husband feel about (your working/the possibility of your working)? Is he very much in favor of it, somewhat in favor of it, neither for nor against it, somewhat against it, or very much against it?"

A nearly identical question was used by Waite and Stolzenberg as an instrument for LFP but was found to be irrelevant; nevertheless, husband's approval is used here as an instrument for LFP. The sample is restricted to couples stably married, 1971–1976, under age 35 in 1972, and having at least one child under age six in 1972 (N = 512).[10]

Results for three models are presented in Table 2. As before, multicollinearity in the LFP equations ranges from high to very high, and the estimated effect of EFS varies accordingly. The most plausible estimate, from Model 2, is that expected family size has no effect on employment plans. A quite different estimate is obtained in Model 3, but not because of greater multicollinearity; sensitivity analysis creates problems of specification error, and these are discussed in a later section. Husband's approval is very strongly associated with wife's employment plans (unlike in Waite and Stolzenberg's data), and multicollinearity is very low in all of the EFS equations. As in the models of husband's expected family size, wife's employment plans depress wife's expected family size by a moderate amount.

The evidence in Tables 1 and 2 mostly supports Waite and Stolzenberg's conclusions. Employment plans clearly seem to depress expected family size. The reciprocal effect may or may not be present but, almost certainly, it is not larger than the effect from LFP to EFS. The instruments for expected family size are, generally, weak, and better ones are needed for more definitive results. Aside from problems of multicollinearity, estimates vary with the specification of the LFP equations, and more care is needed here.

Actual employment and fertility

Smith-Lovin and Tickamyer's model of cumulative employment and fertility cannot be replicated because there is no measure of wife's employment since marriage in the Income Dynamics data. It is possible, however, to estimate an analogous model that adequately represents their

---

[10] The same sample is used for a later model, and the criteria were determined by that use. Husband in the labor force and nuclear family (only husband, wife, and children present) also are criteria for inclusion.

Table 3. Standardized Regression Coefficients from Three Nonrecursive Models of Wife's Labor Force Activity (LFA) and Fertility (FF) during a Six-Year Period, 1968–1973

	LFA As Dependent Variable			FF As Dependent Variable		
	1	2	3	1	2	3
LFA				−.86	.03	.04
FF	−.60	.32	.10			
Wife's employment before marriage	−.07	[a]	[a]	[b]	[a]	[a]
Wife's LF experience, 1968	.25	.23	.21	.21	[b]	[b]
Husband's wage rate	−.21	−.22	−.24	−.19	.02	[b]
Wife's education	.05	.03	.02	.06	.02	.04
Race	.12	.09	.11	.13	.04	.03
Age of youngest child, 1968	.07	.26	.20	−.04	−.21	−.21
Wife's age	−.22	−.00	[b]	−.32	−.24	−.25
Number of children, 1968	−.06	[b]	[b]	−.10	−.06	−.11
Ideal family size	[b]	[a]	−.11	.05	[a]	.13
Catholic	[b]	[a]	[b]	.05	[a]	.10
M^2 of endogenous predictor's instruments	.91	.99	.52	.90	.68	.45
R^2 from first-stage regression	.16	.13	.14	.19	.16	.18

[a] Variable excluded from this model.

[b] Variable excluded from this equation but included in model.

underlying theory by focusing on a segment of married life rather than on cumulative experiences. The endogenous variables are wife's number of years employed from 1968 to 1973 and number of births during the same six-year period. Most of the predetermined variables used by Smith-Lovin and Tickamyer are specified here, although a few have been omitted or replaced because they were irrelevant or unavailable. Wife's employment before marriage (coded 0, 1, or 2 for not employed or employed half- or full-time, respectively) is the instrument for recent employment. Religion and ideal family size are instruments for recent fertility. Wife's education, husband's wage rate, race, and wife's age are joint predictors. Finally, other joint predictors have been added to the model to control for experiences before 1968 (without imposing questionable causal assumptions or constraints), thus making the model comparable to Smith-Lovin and Tickamyer's model. These variables are age of youngest child and number of children in 1968, and wife's years employed from age 18 to 1968. The sample is restricted to couples stably married, 1968–1976, wife under age 35 in 1968, and having at least one child under age six in 1968 (N = 442).[11]

Results for this model are presented as Model 1 in Table 3. All of the instrumental variables are weak, and multicollinearity is very high (M^2 over .90). The coefficients for the endogenous predictors are quite large in absolute value, and other coefficients also are implausible. Very clearly the model is inadequate. Results are even worse if the controls for initial conditions (age of youngest child, number of children, work experience) are omitted.

The logic of Model 1 is that early experiences influence subsequent behavior (if religion and ideal family size can be interpreted as fertility norms and preferences learned during adolescent socialization). Model 2 tests whether the instruments used in Model 1 are simply too remote temporally. In Model 2 the earlier instruments are dropped, and wife's work history up to 1968 and number of children in 1968 are used as instruments. Results for this model are not much better than for Model 1, with continued high multicollinearity and implausible estimates.

A major difficulty with Model 2 is the high correlation between wife's age and number of children in 1968 (r = .59). The impact of multicollinearity on the entire model is reduced if both variables are used as instruments for fertility.[12] Religion, also, is used as an instrument in Model 3, but ideal family size is specified as a joint predictor because it could reflect beliefs about female employment as well as about fertility. Husband's wage rate is shown in Model 3 as an instrument for wife's employment. This is an empirical expedient to reduce multicollinearity, not a theoretical proposition. In several alternative specifications of Model 3, husband's wage rate was strongly related to wife's employment, but not to fertility (as in Model 2); and using it as an instrument has little effect on the estimates, but improves their stability. Multicollinearity is greatly reduced in Model 3, and most coefficients have plausible signs and magnitudes. In this model there is no direct causal link between actual employment and fertility; both are determined by interrelated prior events and characteristics.

---

[11] Wife's employment and fertility are not counted up to 1976 because in this sample there were very few births after 1973. Wife's age could not be restricted more so as to be comparable to Smith-Lovin and Tickamyer's sample and still maintain a large enough sample, but there is nothing in their particular theory that would suggest that the discrepancy is important. Husband in the labor force and nuclear family also are criteria for inclusion.

DYNAMIC BEHAVIORAL MODELS

The results in Table 3 do not support Smith-Lovin and Tickamyer's conclusion that cumulative fertility strongly affects cumulative labor force experience; nor is there any good evidence of a reciprocal effect. The main finding is that the estimates are very sensitive to the model's general specification. It has become clear that this is more than just a problem of multicollinearity (although the latter is not at all negligible), and we turn now to the more general problems.

Specification Problems

A major difficulty with the Smith-Lovin and Tickamyer model is its ambiguous theoretical structure. Clearly, the model depicts behavior, but it is not clear that it depicts dynamic processes. There is no temporal relationship between cumulative fertility and employment and, indeed, the endogenous variables are nearly as static as the "lifetime decisions made at marriage" that characterize most microeconomic models. Dynamic models make essential references to time lags and intervals. Smith-Lovin and Tickamyer specify background variables and controls for marriage and premarriage durations, but these are weak references to time. Hout's model (1978), in contrast, specifies 3-year lagged fertility and employment variables and, clearly, is a dynamic model of behavioral processes. Recently, there have been numerous criticisms of the static nature of microeconomic models and appeals for dynamic models (Bagozzi and Van Loo, 1978; Heckman and Willis, 1976; Hout, 1978; Masnick and McFalls, 1976; Namboodiri, 1972; 1974; 1975; Rosenzweig, 1976; Ryder, 1973). Smith-Lovin and Tickamyer's attention to behavior is a welcome—but insufficient—step in the right direction, and Cain's reworking of the same data (1979) is only a partial improvement in this regard.

A dynamic model of cumulative employment and fertility can be specified with the data used in Table 3. Among the couples who had babies between 1968 and 1973, the exogenous variables are measured in the year preceding birth; and wife's employment is measured both before and after birth.[13] Among couples who did not have babies, the same temporal sequence of measurements is followed, using 1970 as "the year the baby was not born." This model is used to estimate whether prior employment determined who had a baby (called "fertility status"), whether fertility status determined subsequent employment, and what effects the exogenous variables had on both behavioral sequences. The model consists of unambiguously ordered behavioral sequences (plans and expectations are studied in a later section), and it is recursive, so there is no difficulty with instrumental variables.[14] Centering the measurements around the time of birth eliminates the confusion caused by timing decisions and directs attention to the important questions of who has a baby and does a baby affect wife's employment.[15]

---

[12] This does not reduce the correlation between age and parity, of course, but it eliminates other, more critical, sources of multicollinearity in the second stage of 2SLS.

[13] In the present dynamic model fertility and employment are measured during calendar years with one-year lags; for example, employment is measured in 1969 and 1971 for a birth during 1970. Alternative models with two-year lags between initial employment and fertility, and with initial employment status (a dichotomy) lagged one and two years, give similar results as those reported here, so one year seems to be an appropriate lag for decisions about pregnancy, abortion, and birth (and it is unlikely that there is a reciprocal effect of pregnancy on initial employment). For couples with two or more babies from 1968 to 1973, employment is measured before and after the first of these babies. In 22 cases, the second baby was born the year following the first; because of the difficulty in measuring post-birth employment, these couples are excluded from the sample.

In the attempts above to replicate other models, little was said about the exogenous variables; but more care is needed now. In dynamic behavioral models, the endogenous variables represent changes in initial conditions, so our exogenous variables must include measures of the wife's initial "stocks" of fertility and employment, both current and cumulative: number of children, age of youngest child, and years employed since age 18 (as well as initial or prebirth employment). Wife's age, race, and religion also are essential to the model. Husband's approval of wife's employment and other attitudinal variables are omitted here, but are examined later. Macrolevel demand for labor probably influences individuals' decisions, but the measures available—county unemployment rate and county labor force participation rate of married women, both taken from 1970 census data—are not the most appropriate variables and are largely irrelevant in our models. Because of its theoretical interest (Bowen and Finegan, 1969; Cain and Dooley, 1976), the latter variable is included in the model anyway as a proxy for the local demand for female labor. Other variables were considered but have been omitted on empirical grounds in order to keep the model simple: wife's age at marriage was highly correlated with other variables and added little to the model; farm background, number of siblings, and husband's unemployment also were irrelevant, though not because of high correlations with other variables.

Spouses' abilities to earn income are prominent predictors in microeconomic theories of employment and fertility, but there is little agreement about how to measure them. Both Smith-Lovin and Tickamyer and Waite and Stolzenberg use husband's annual earnings to measure financial pressures on the wife, and wife's education to measure her incentive to work, but economists generally consider these to be inappropriate measures. A predicted (or potential) wage rate for the wife usually is advocated in place of education.[16] Husband's earnings reflect endogenous decisions about hours worked as well as transitory constraints (for example, unemployment) and measurement errors; and current earnings may not accurately indicate expected purchasing power in the future, as the children grow up. Finally, identical levels of husband's earnings represent different financial pressures in different sizes of families.

A variety of income measures have been proposed to solve these problems. Potential income, constructed from husband's wage rate, removes variations in hours worked. Permanent income is either a short-term average, eliminating errors and random fluctuations, or a predicted future value (for example, income expected at age 40) that incorporates trend, as well as current income level. Income adequacy is a measure of income standardized for the basic consumption needs of the husband's family, based mainly on family size and composition.

Various combinations of these measures of husband's earnings can be estimated with Income Dynamics data; they are described and summarized in Table 4. All monetary variables are adjusted to

---

[14] This is true only because the problem of autocorrelated disturbances in the employment equations is being ignored until a later date. The statistical models available to handle this problem are not yet clearly established (Cook and Campbell, 1979; Hannan and Young, 1977; Hibbs, 1974).

[15] Average birth intervals are about two years (Ryder and Westoff, 1971), so probably few couples with an open birth interval of at least six years are still postponing another baby.

[16] Hout (1978) discusses some of the biases inherent in this approach. Wife's wage rate is assigned here on the basis of a nonlinear, nonadditive model estimated for employed wives using wife's education and work history, age, race, farm background, husband's wage rate, county unemployment rate, and county labor force participation rate of married women.

Table 4. Summary of Alternative Measures of Economic Predictors: Definitions, Means, and Partial Correlations with Wife's Initial Hours Employed and Fertility Status

				Partial Correlation[b]	
Name	Description	Definition[a]	Mean	Hours Employed	Fertility Status
HWAGE	Husband's wage rate	Average hourly earnings	4.23	−.10	.00
HEARN	Husband's earnings	Annual earnings	9965	−.11	.03
HIAD	Income adequacy	HEARN/NEED	2.56	−.15	.04
PIAD	Potential income adequacy	HWAGE • 2400/NEED	2.62	−.13	.03
AVEW	Average wage rate	9-year average, 1967–75	4.51	−.15	.09
AVEIA	Permanent wage rate adequacy	AVEW • 2400/NEED	2.85	−.18	.12
TREND	Average annual increase in wage rate during 1967–75.	Slope from regression of wage rate on year	0.14	−.06	.09
TRENDIA	Average annual increase in current income adequacy	TREND • 2400/NEED	.089	−.07	.10
TRENDAV	Relative wage rate trend	100 • TREND/AVEW	2.82	−.02	.07
TRENDHW	Current relative trend	100 • TREND/HWAGE	3.93	−.01	.09
WAGE	Wife's potential wage rate	Assigned from regression model	2.21	−.12	.01
ED	Wife's education	Years of schooling completed	12.0	−.04	.04

[a] NEED is the Social Security Administration's estimate of basic consumption needs based mainly on family size and composition (Duncan and Morgan, 1976). All monetary variables are adjusted to 1969 dollars (before construction of economic predictors). Unless otherwise indicated, measures are defined for the year preceding birth.

[b] In the employment model the variables controlled are initial family size, age of youngest child, wife's years worked since age 18, wife's age, race, and religion. In the fertility status model, initial employment also is controlled.

1969 dollars. The longitudinal data are used to estimate trends directly (by regressing annual real wage rates on time for 1967–1975 for each husband), thereby avoiding predictions based on other cohorts' experiences. The partial correlations between these measures and wife's initial hours employed and fertility status, controlling for the other exogenous variables, are shown for comparison and evaluation. Partial correlations for wife's potential wage rate and education also are compared in Table 4. In general, standardizing for income needs and averaging several years' values both seem to improve the predictive power of husband's wage rate.[17] Trends, no matter how they are standardized, do not predict as well as average wage rate levels in this sample.[18] The superiority of husband's average wage rate standardized for needs (AVEIA) over conventional single-year income measures, or measures of trend; persists in most of the models reported in this and the following section; the figures in Table 4 are typical of these general results. Often, results for AVEIA (called "permanent wage rate adequacy") are significant and consistent with economic theory, while results for annual wage rate or earnings are negligible or inconsistent, indicating the importance of correctly specifying variables. Wife's potential wage rate is used in our models rather than education both because it predicts better and because it is theoretically preferable.

A final specification issue is interaction effects. For example, Hout (1978) and Namboodiri (1972; 1974) argue that the determinants of additional fertility are different for women at different initial parities, because of strong normative pressures to have at least two children and because of (presumed) rapidly declining marginal satisfactions from high-order births.[19] An additive model will be estimated first and then used to test for parity and other types of interactions.

---

[17] It is assumed here that husband's wage rate is not affected by having a baby, but that future wage rates are anticipated and can influence fertility decisions (Cramer, 1979b; 1979c). Standardizing for income needs is a valid use of initial conditions in dynamic models but is never seen in static life cycle models.

[18] Trend is irrelevant when average level is controlled, but the converse is not true. Income trend might be more relevant in a sample of younger, recently married, less economically established couples. Controlling for wife's potential wage rate increases the partial correlations of trend and other husband's measures, but does not change their rank order; the correlation between WAGE and AVEIA is .63.

Results

Estimates are shown in Table 5 for a recursive model of wife's initial hours employed, fertility status, and subsequent hours employed. Very similar results are obtained if wife's employment status is used instead of hours worked. The equation for initial employment is a standard cross-sectional model of labor supply, and the coefficients are in the expected directions with the expected relative magnitudes. The main determinants of initial employment are financial pressures, demographic constraints, and prior work experience. There is a large racial difference in initial employment, but the standardized coefficient for race is not especially large because the sample is predominantly nonblack. Wife's potential wage rate has little effect on labor supply; a similar result is found with wife's education, and the result conforms with past research (Cramer, 1979a; Sweet, 1973).

Table 5. Standardized Regression Coefficients from a Recursive Model of Wife's Fertility Status from 1968 to 1973 (DFF) and Hours Employed Before (BLF) and After (ALF) Having a Baby (or "Not Having a Baby in 1970")

	BLF	DFF	ALF
Fertility status (DFF)			−.21
Employment before birth (BLF)		−.12	.52
Husband's permanent wage rate adequacy	−.14	.22	−.02
Wife's potential wage rate	.02	−.13	−.01
Age of youngest child	.20	−.13	.06
Number of children[a]	−.05	.01	.01
Wife's years worked since age 18	.43	.08	.15
Wife's age	−.35	−.35	−.04
Race	.16	.02	.07
Catholic	−.01	.05	.01
County labor market for women	.10	−.02	.02
R^2	.27	.21	.46

[a] Number of children in 1968 is dichotomized (1 or 2 children, and 3 or more) so as to be consistent with subsequent tables.

The second equation in Table 5 predicts who has another baby. The main determinant, of course, is wife's age; undoubtedly, this reflects subfecundity as well as the growing cultural preference not to have children after age 35 (Ryder and Westoff, 1971). Wife's initial employment depresses fertility slightly but significantly; the estimate here is somewhat larger than those by Hout (1978) and Smith-Lovin and Tickamyer (1978). The unstandardized coefficient is −.08, indicating that the percentage of couples who had a baby was 8% lower for each 1,000 hours of initial employment (for example, the difference between half-time and full-time employment), other things being equal. About half the sample (53%) had a baby, so the effect of initial employment is not trivial. There is no discontinuity or nonlinearity "at the corner," to differentiate nonemployed women from women with very low levels of employment.[20] One would expect a discontinuity if the effect of employment were due to sex role attitudes or tastes, so initial employment is best interpreted as an opportunity cost. This interpretation is buttressed by the small effect (in the opposite direction) of wife's prior work experience, which is much more likely to represent tastes than opportunity cost; the effect is even smaller if current (initial) employment is omitted from the equation. Furthermore, age of youngest child is moderately related to subsequent fertility; this may be interpreted both as a sign of subfecundity and as another measure of cost (Cain, 1979; Lindert, 1978; Turchi, 1975a). Finally, husband's financial well-being encourages fertility while wife's potential wage rate (another measure of cost) discourages it, consistent with microeconomic theories of fertility.[21] The estimates may be somewhat exaggerated by multicollinearity, but from Table 4 there is no doubt that husband's potential wage rate adequacy has a positive effect.

---

[19] Stolzenberg and Waite (1977) argue that the interactions are due to maturation and learning associated with wife's age, not parity. The theoretical issues are complex. In exploratory tests with the present model parity interactions were found to be substantial but not age interactions (by themselves or within parity groups), so age interactions are ignored here.

[20] Corner solutions are described by Cramer (1979a). The results for the employment corner solution are not shown in Table 5, but the relevant F-value is 0.2 (without correction for design effect, heteroskedasticity, etcetera).

The third equation, predicting wife's employment after having a baby (or after "not having a baby" in 1970), is more easily summarized. Having a baby substantially reduces wife's employment, as shown also in past research (Cramer, 1979a; 1979c; Smith-Lovin and Tickamyer, 1978). In addition, employment depends on initial employment and prior work experiences, but not on any of the other variables in the model. In this equation there is a significant discontinuity "at the corner" of initial employment: wives who were not employed initially had much lower subsequent employment than wives who were initially employed only a little. This is evidence of a tendency for wives to remain either employed or not employed, according to individual preferences more than to "market forces," and supports Heckman and Willis's (1977) bipolar "mover-stayer" model of labor supply. These results reinforce the interpretations of the fertility equation.

The most important results in Table 5, for present purposes, are that wife's employment and fertility each affect the other, but the effect of fertility on employment is relatively greater. In addition, both variables are determined jointly by exogenous factors such as financial status, age of youngest child, and wife's age. Nearly identical results are obtained if wife's employment status is used in place of hours worked, although its effect on fertility (−.07) is less than the effect of hours worked (−.12) while the reciprocal effect of fertility is the same. Most past research has used information on employment status but not on hours worked, so the effect of employment on fertility has been underestimated.

Hout's (1978) hypotheses regarding differences by parity in the determinants of fertility and employment are plausible but are not soundly based on theory, so parity interactions will be presented here as empirical regularities for which there are not yet good explanations. In order to investigate interactions, the dynamic model was estimated first among couples with only one or two children initially (two-thirds of the sample), and then among couples with three or more children.

In the equation predicting fertility, Hout (1978) suggests that husband's permanent income should be important only at low parities (due to timing of births); wife's potential wage rate should be more important at higher parities (where norms have been satisfied and costs become important); and age should be more important at lower parities (for unclear reasons). His results are consistent with all three hypotheses. All three hypotheses also are confirmed with the present models. The metric coefficients for husband's permanent wage rate adequacy in the low and high parity samples are .103 and .025, respectively; for wife's potential wage rate, −.069 and −.210; and for wife's age, −.054 and −.009. Interaction effects involving other predictors in the model have not been reported in past studies, and none of any importance or interest was found here.

In the equation predicting employment, Hout found that both prior employment and fertility have greater effects at higher parities. In our model, also, the effect of initial employment on subsequent employment is larger in the higher parity subsample, but not by much (coefficients of .545 and .619, respectively). The difference is small, partly because of the inclusion of wife's work history in our model, which also is more important at higher parities. When the effects of work history are constrained to be the same (as in Table 6), the coefficients for initial em-

---

[21] Because wife's potential wage rate is an assigned value from a regression model estimated with a different sample, its variance is underestimated by an unknown amount and, thus, its standardized coefficient also is underestimated (Hout, 1977). An alternative measure of relative importance that is unbiased is elasticity at the mean. By this criterion, wife's potential wage rate (−.45) is at least as important a predictor as husband's permanent wage rate adequacy (.38).

Table 6. Unstandardized Regression Coefficients from Recursive Models of Wife's Hours Employed in 1975, 1974, and the Year Following Childbirth: Full Sample of all Wives, and Subsample of Wives with, at Most, One Baby from 1968–1973[a]

	Full Sample, Just After Childbirth	Subsample, At Most One Baby		
		Just After	1974	1975
Fertility status				
If 1 or 2 children[b]	−393	−363	−384	−349
If 3 or more children[b]	−222	−248	−220	−153
Employment before birth, (000)				
If 1 or 2 children[b]	520	574	456	360
If 3 or more children[b]	663	693	476	366
Husband's permanent wage rate adequacy	−10	4	−26	1
Wife's potential wage rate	−14	−54	−121	−148
Age of youngest child[b]	22	12	−5	−6
Number of children[b]	−120	−86	−46	−74
Wife's years worked since 18[b]	27	27	29	44
Wife's age[b]	−9	−6	−10	−14
Race	162	161	287	238
Catholic	18	21	43	44
County labor market for women[b]	2	−3	2	11
Open birth interval			23	89
R^2	.47	.49	.35	.27

[a] The full sample, used for Table 5, includes 420 respondents. The subsample excludes couples who had a baby in 1974 or 1975 and couples who had 2 or more babies 1968–1973, leaving 347 respondents.

[b] These variables are measured the year before childbirth. Number of children (initially) is dichotomized for the sake of specifying interactions. The coefficient for number of children is an intercept (constant) for the interaction terms, unlike in Table 5.

ployment are substantially different. Hout's results for the effects of fertility conflict with past studies (Lindert, 1978; Turchi, 1975a). In our model, the effect of a baby on subsequent employment is smaller at higher birth orders (coefficients of −413 and −233), consistent with the other studies rather than with Hout. As in past research with these data (Cramer, 1979a; 1979c), the difference between birth orders is not significant. Thus, although our results replicate most of Hout's, the one interaction effect of direct relevance here (the effect of fertility on employment) is not replicated—and, indeed, is in the opposite direction, and is not significant. There are no parity differences in the effect of initial employment on fertility.

The above estimates of the effect of a baby on wife's employment are measured when the baby is about one year old. Both cross-sectional and longitudinal studies (Bowen and Finegan, 1969; Cramer, 1979c; Lindert, 1978) have indicated that the effect of a baby may decline as the baby becomes older. The model in Table 5 can be modified to study this possibility, although for convenience the sample must be limited to couples who had at most one baby from 1968 to 1973 and no babies in 1974 and 1975.[22] The modifications are to measure wife's employment in 1974 and 1975 as well as the year following birth, and to control for the number of years from birth to 1974 and 1975 (that is, open birth interval, or age of youngest child). As before, among couples who did not have a baby, employment "before birth" is measured in 1969, and open interval is measured from 1970. In 1975, the open interval ranged from two years to seven years with a mean of 5.1. Results for equations predicting wife's hours employed the year following birth and in 1974 and 1975, showing the effect of a baby from age one to average age five, are presented in Table 6. Parity interaction effects are shown for fertility status and initial employment. Unstandardized coefficients are used to permit comparisons across equations. Unstandardized coefficients also are shown for the "year after birth" equation for the full Table 5 sample.

---

[22] Forty-seven couples are excluded from the Table 5 sample because they had more than one baby during 1968–1973, and an additional 26 are excluded because they had a baby in 1974 or 1975 (ten of whom had not had a baby during 1968–1973), leaving 347 couples in the Table 6 subsample.

The effects of most variables are approximately the same in the full sample and the subsample the year following birth and in the subsample at the three points in time. The coefficients for wife's potential wage rate are not significantly different in the four equations and show signs of being somewhat distorted by multicollinearity, so the apparent differences probably should be disregarded. The coefficients for race clearly show the more rapid labor force reentry by blacks (Sweet, 1972). By 1975, the coefficient for open interval is about the same as the coefficient for age of youngest child in the prebirth cross-sectional model of labor supply in Table 5, suggesting that the dynamic model is approaching stability five years after the "shock" of childbirth.

The effect of employment before birth on subsequent employment clearly diminishes over time as intervening events and contingencies become more common and more important (reflected also in declining values of R^2). In addition, the difference in this effect between parities diminishes over time and disappears in four years (from "after birth" to 1975).

The most important results in Table 6, for fertility status, also are the most difficult to interpret. Among couples who already had at least three children, the effect of another baby on wife's employment declines as the baby ages, particularly as the baby approaches school age (from 1974 to 1975). Among couples with only one or two children initially, however, there is no apparent trend in the effect of another baby. According to the available estimates of standard errors (which are biased and unreliable), the differences in effects of fertility status between parity groups and between equations are not significant. If, however, the coefficients are more reliably estimated than are the standard errors, then a consequence would be that estimates of the effect of fertility on employment would be smaller if samples are drawn at more advanced life cycle stages, or if the reference is to expected family size rather than to current family size (thus, somewhat clarifying Waite and Stolzenberg's results). This issue may deserve further research.

A DYNAMIC MODEL OF PLANS AND BEHAVIOR

The preceding models assume that people act spontaneously, subject to constraints from past actions and influences but without foresight or expectations. Certainly the models are incomplete, as people do respond to anticipated future conditions. Anticipations and plans affect behavior in two principal ways. First, they may affect actual causal relationships; for example, the effect of a baby on employment may depend on whether fertility status was planned or accidental (that is, unwanted pregnancies or sterility). Second, plans may not affect causal relationships within behavioral sequences but they may determine the number of such sequences. For example, fertility plans may not alter the impact of a baby, but they may determine how many babies are born. In this case, a major issue is whether plans are exogenous or are subject to revision pending behavioral experiences.

Employment and fertility plans were examined briefly, in Tables 1 and 2. The results resemble past research and, thus, establish the credibility of the data, but, otherwise, those models are unsatisfactory because they ignore the processes by which plans are formed. Incorporating plans into dynamic behavioral causal models is a formidable theoretical challenge. A modest beginning can be made with the Income Dynamics data by making strict use of temporal sequences. It is assumed that plans stated in 1972 causally precede behavior between 1972 and 1975, which, in its turn, causally precedes revised plans stated in 1976. Thus, for example, it is assumed that expected family size is reliably reported and that, over time, this expectation may change—that is, the 1972 and 1976 responses are not simply inaccurate measures of the same underlying, immutable Goal.[23] Substantial

---

[23] With these data it must also be assumed that spouses have identical expectations or that they re-

Table 7. Standardized Regression Coefficients from a Recursive Model of Wife's Fertility Status from 1972 to 1974 (DFF), Hours Employed before (BLF) and after (ALF) Having a Baby (or "Not Having a Baby in 1973"), and Hours Employed in 1975 (LF75).

	BLF	DFF	ALF	LF75
Fertility status (DFF)[a]			−.14	−.15
Employment before birth (BLF)		−.09	.52	.38
Husband's permanent wage rate adequacy	−.21	−.07	−.08	−.13
Wife's potential wage rate	.16	.07	.03	.09
Age of youngest child	.08	.06	.11	.19
Number of children[b]	−.07	−.24	−.01	.01
Wife's years worked since age 18	.45	−.01	.19	.16
Wife's age	−.29	−.14	−.21	−.25
Race	.07	.05	.02	.03
Catholic	−.06	.06	.01	.03
County labor market for women	.06	.10	−.02	−.04
R^2	.30	.10	.48	.35

[a] In the LF75 equation DFF is coded 2 for the 8 couples who had babies in both 1972 and 1974. In the ALF equation it is coded 1 for these same couples because ALF is measured after the first of these two births (that is, in 1973).

[b] Number of children is dichotomized, as in Tables 5 and 6.

support for these assumptions exists (Bumpass and Westoff, 1970; Hout, 1978; Namboodiri, 1972; 1974; Ryder, 1978), although alternative assumptions also are plausible and may be investigated elsewhere.

With these assumptions, dynamic recursive models of plans and behavior can be constructed from data on births from 1972 to 1974, employment in 1975 (after birth) as well as before birth, and expected labor force activity and fertility reported both in 1972 and in 1976. The sample used earlier to analyze 1976 plans (Table 2) is used again here, although couples with births in consecutive years or in 1975 have been excluded (N = 461). In this sample, plans and behaviors are related but distinct. Nearly 40% of the sample in 1972 expected to have more children, 29% did have another baby by 1974 and, in 1976, 14% still expected more children. In 1972, 54% of the wives expected to be employed "in the next few years" (42% actually were employed before birth). The correlation between wife's expected employment and expected family size in 1972 is −.12, but the correlation between expected employment and expected additional births is .14. In 1976, 72% expected to be employed soon; the correlation between employment plans in 1972 and 1976 is only .28.

Because of data limitations, the sample and model used here differ in several important respects from those used in the previous section to anlayze dynamic behaviors, and the present task is more complicated than merely adding plans to the previous model. Births during a six-year-period were studied above; most couples who were going to have a baby did so in that time interval, so the problem of confounding quantity and timing of births was slight. Here, because plans were ascertained only in 1972 and 1976, births during a three-year-period are studied. The equation for fertility status predicts decisions both to increase family size and not to postpone having the baby. A second difference is changed historical circumstances. For example, 53% of the 1968–1973 sample (Table 5) had a baby during the period of observation compared with 29% of the 1972–1974 sample; the difference is due both to the different time durations and to the accelerating decline in fertility from 1967 to 1975. Because of these differences, it is necessary to begin by comparing Table 5 with the same behavioral model estimated for the more recent sample (1972–1974 births), shown in Table 7.

The equation for hours employed before birth (BLF) in Table 7 is reasonably simi-

---

port the compromise, "couple's expectation," because expected family size was reported by the husband in 1972 and by the wife in 1976.

lar to the BLF equation in Table 5. In all cases, the coefficients have the same sign, and in both samples wife's age and work experience are the most important predictors of BLF. The magnitudes of several coefficients differ in the two samples, but these differences seem to be due to small differences in simple correlations in the two samples and can be attributed mostly to chance sampling fluctuations or measurement errors.

The effect of initial employment on fertility status (DFF) is the same in both samples. In both samples, also, older women were less likely to have another baby, but the importance of wife's age is much less in the 1972–1974 time period (Table 7). This may be due to historical conditions that affected timing decisions. Ward and Butz (1978) argue that births were compressed or accelerated from 1967 to 1972 and were being postponed from 1972 to 1975. Younger wives are much more likely to postpone births (because they have time to make them up), so the age difference in fertility diminished during this time period. Other differences between the DFF equations in Tables 5 and 7 seem to be due to high correlations between age and other variables and to sampling fluctuations magnified by multicollinearity. For present purposes, however, the most important conclusion is that the effect of prior employment (BLF) is the same in both samples.

The determinants of wife's employment after having a baby (ALF) are fairly similar in the two samples. Initial employment, work history, and fertility status are among the most important predictors in both samples and have consistent effects (same signs, similar magnitudes). The impact of a baby is smaller in the more recent sample, but the difference disappears when the earlier sample also is restricted to births during a three-year period (Cramer, 1979c) so it may be an artifact of timing decisions. The impact of a baby is due partly to increasing employment among wives who do not have a baby; the increase may be less if babies are simply being postponed. The reasons for the greater importance of age in the 1972–1974 sample are unclear, although clues may be found in trends in age specific female wage rates (Ward and Butz, 1978:49–51) and in the changing relationship between age and fertility discussed earlier. Coefficients for other variables are similar in the two samples.

Table 7 also includes a comparison of equations for wife's employment in 1975, and just after having a baby. As expected, the effect of initial employment is smaller at the more distant sequel (1975). Other variables have similar effects in the two equations.

The analysis of Table 7 indicates that fertility timing decisions and historical circumstances do affect the behavioral model, but that the major problems are with the exogenous variables. Relationships between employment and fertility are relatively robust and stable across samples, so plans can usefully be incorporated into the model, as long as attention is focused on these endogenous variables. Plans in 1972 are specified as correlated exogenous variables, and plans in 1976 are specified as outcomes of earlier plans and intervening behavior. In order to simplify the model, differences between initial parity groups are not reported and parity is not dichotomized; interactions with exogenous variables make little sense in this sample because of unclear patterns of fertility timing decisions, and interactions with endogenous variables give results very similar to those in Table 6. Results for the additive recursive model of plans and behavior are presented in Table 8.

Number of additional births expected in 1972 is a very strong predictor of actual births during 1972 to 1974. Most other variables affect fertility status only through their effects on fertility plans. About 10% of the couples who did not expect more children had a baby while 40% of the couples who expected more did not have a baby (yet), so most of the gap between planned and actual fertility is due to time truncation, deliberate postponements, and downward revisions of plans. Employment plans in 1972 had essentially no effect, directly or indirectly, on subsequent fertility. Actual employment before birth, however, is significantly associated with fertility status: employment plans, fertility plans, and other factors being equal, wives who worked more hours were less

Table 8. Unstandardized Regression Coefficients from a Recursive Model of Expected Family Size (EFS76) and Labor Force Plans (LFP76) in 1976, Wife's Hours Employed in 1975 (LF75), and Fertility Status from 1972–1974 (DFF)

[a] DFF as a dependent variable is dichotomous, but as a predictor it is number of babies born (only 8 couples had 2 babies).

[b] Fertility plans in 1972 are dichotomous in the DFF equation and "number of additional children expected" in the other equations.

[c] Employment plans in 1972 are measured the same as in 1976: working at the time of interview or plans to work in the near future (dichotomous).

[d] Unlike in Tables 5–7, number of children (initially) is not dichotomized.

likely to have a baby. In addition, this relationship differs by planning status. Among couples who expected no more children, employment before birth is not related to fertility status (suggesting that the births were truly accidental). Among couples who expected more children, the effect of employment is −.108, larger than the average estimate in Table 8: other things being equal, the proportion of wives who had a baby was 11% lower, on average, for each 1,000 hours worked (the difference between full-time and half-time employment). The same effect of employment before birth is found for expected family size in 1976, so it indicates reduced (rather than delayed) fertility.

Employment in 1975 is unrelated to both employment plans and fertility plans in 1972, so the estimates for this equation in Tables 7 and 8 are similar and need little discussion. Employment in 1975 is strongly related to fertility status, prior employment, and economic pressures and incentives. The effect of fertility status does not depend on whether more children were expected in 1972. Too few couples expected more births, after 1976, for us to test the related conjecture that the effect of having a baby depends on whether it is the last child expected.

The main determinants of expected family size in 1976 are cumulative fertility (initial parity and additional births, with nearly equal effects), demographic constraints (wife's age and age of youngest child initially), race, and religion. Fertility plans in 1972 have a small additional effect, but employment plans in 1972, and actual employment in 1975, are irrelevant. As noted above, employment before birth does reduce expected family size in 1976. Because current family size is controlled, results for additional births expected in 1976 are identical to these results for expected family size.

Employment plans in 1976 depend mainly on actual employment after birth (in 1975), but earlier employment plans, wife's potential wage rate, and age also are significant. Prior expected and actual fertility have negligible effects on employment plans. Similar results are obtained in a second equation for employment plans in which actual employment is omitted, indicating that the fertility variables are not very important even indirectly. Conclusions from these results, however, must be qualified by the observation that none of the variables explains employment plans very well (that is, R^2 is small), undoubtedly due in part to the very crude way in which employment plans are measured.

The main conclusion to be drawn from Table 8 is that both employment plans and fertility plans depend primarily on recent behavior—employment plans on employment, and fertility plans on fertility.[24] In both cases there is little "cross-over," in the sense of one type of behavior affecting the other type of plan. Prior plans have only small direct effects on current plans, again with no cross-over. The recent behaviors, on which current plans depend, generally do not themselves depend on earlier plans, with the major exception of the strong relationship between expected family size and fertility. Rather, recent behaviors mainly depend on earlier behaviors (and exogenous factors).

Employment and fertility do not seem to be related by way of plans and expectations. There are two behavioral links, both noted in the previous section. First, employment before birth tends to reduce the probability of having more children. This effect is relatively strong among couples who expect more children and it is absent among couples who expect no more children.[25] Second, having a baby strongly depresses employment. This is true regardless of fertility expectations. The effect of a baby on actual employment seems to decline as the child becomes older, and the effect on employment plans is negligible. Thus, in the short run, fertility has a strong effect on employment, but, in the longer run, the effect of employment on fertility may be stronger.

Brief mention should be made of several other types of attitudes and expectations. Husband's attitude toward wife's employment was defined above in connection with Table 2. Wives also were asked in 1976:

> "How does your husband feel about having (more) children? Is he very much in favor of it, somewhat in favor of it, neither for nor against it, somewhat against it, or very much against it?"

This question is particularly interesting because expected family size was reported by husbands in 1972 and by wives in 1976. Both attitudes contribute significantly to the model of 1976 expectations,[26] but in very limited ways. Husband's support for his wife's employment is strongly related to her employment plans, but controlling for his attitude has no impact on the effects of other variables, and his employment attitude is unrelated to expected family size. Similarly, his reported desire for more children significantly affects expected family size but does not change the effects of other variables, and it is unrelated to wife's employment plans. Thus, incorporating these attitude items into the models does not change the results, but it tends to reinforce the impression that fertility plans and employment plans are not strongly related.

Finally, Butz and Ward (1977), Lindert (1978), and Willis (1973) have argued, in different ways, that the determinants of fertility are different depending on whether the wife intends ever to be employed or not. Eventual intentions were not asked in the Income Dynamics study. As an approximation, wives with under three years of employment experience since age 18, and who reported in both 1972 and 1976 no intention to seek employment soon, were excluded from the sample (39 cases). Models estimated for the remainder of the sample do not differ noticeably from Tables 7 and 8, so this hypothesis does not seem to be supported.

---

[24] The correlation between residuals from the 1976 expected family size and employment plans equations is .09, indicating that probably there is little simultaneous dependence between the two 1976 plans.

[25] It is assumed in this paper that the results indicate a causal effect of employment on fertility. An alternative interpretation (which cannot be tested with the available data) is that employment interacts with historical trends and cycles but does not, itself, cause fertility. The aggregate decline in total fertility rate and expected family size during the years of the Income Dynamics study may have occurred for reasons that are unrelated to the processes specified in our models, and employed wives may simply have responded to these historical trends first, or most enthusiastically. This would imply that the effect of employment on fertility is different under different historical circumstances.

[26] The attitudes are not used to predict actual behavior because of our adherence to strict temporal sequences. An alternative treatment is presented elsewhere (Cramer, 1979c). The correlation between the two attitudes is .03.

CONCLUSIONS

The dynamic models in Tables 6 and 8 permit a partial resolution of the debate about causal direction between fertility and wife's employment, but, as always, a complete synthesis must await further research. As many demographers have suspected (but recent research failed to show), causation appears to go in both directions. Certainly, in the short run, fertility has a large impact on wife's employment which overshadows any impacts in the opposite direction. The same result was obtained by Smith-Lovin and Tickamyer (1978), but their evidence is shaky because of the high likelihood of serious problems of multicollinearity. In addition, they probably underestimate the reciprocal effect of employment on fertility by counting years of employment but not hours per year. Finally, they tend to exaggerate the effects of fertility because their model emphasizes short-run impacts, as they readily acknowledge.

Estimating the impacts of fertility on employment is difficult because there may be several different types of impact. We have found that the effect of a baby does not depend on whether it was expected, but, as in previous research (Cramer, 1979a; 1979c), evidence on differences between birth orders is not conclusive. A more serious issue is that of distinguishing between the impact of an extra child and the effects of age of youngest child. Results reported here, and elsewhere (Bowen and Finegan, 1969; Cramer, 1979c; Lindert, 1978; Sweet, 1973), indicate that the impact of a baby declines rather sharply as it approaches school age, at least among higher birth orders. It seems very likely that most of the impact of a baby is due to its young age (except possibly with adoptions), and that, in the long run, the impact of fertility on employment may be relatively slight (depending, of course, on whether one measures annual or cumulative employment).

Waite and Stolzenberg rely heavily on this long-run argument to explain their finding that the dominant direction of causality is from expected labor force participation to expected family size. Our quasi-replications of their model give quite similar results with both 1972 and 1976 data on fertility and employment plans, despite moderate to high levels of multicollinearity. But the dynamic models of causal processes suggest that the static model of long-run plans is as misleading as it is correct. The main difficulty is that employment plans appear to be largely irrelevant; they generally have very little effect (directly or indirectly) on fertility status, actual employment after birth, and subsequent employment and fertility plans.[27] Actual employment, on the other hand, does reduce actual and expected fertility. This effect builds over time (as initial employment and reduced fertility both stimulate higher subsequent employment) so that, in the long run, employment may have a substantial effect on fertility. This process is influenced by exogenous factors such as economic incentives and pressures, but net of such factors there is no evidence that the long-run impact on expected or actual family size is a premeditated consequence of employment plans.

Fertility plans, on the other hand, are strongly related to actual fertility, although fertility status certainly is not completely planned, and plans can change. In addition, the effect of employment on fertility depends on whether more children are expected. Otherwise, fertility plans are important only indirectly through the effects of actual fertility. In particular, initial fertility plans are only weakly correlated with initial employment plans and have no direct effect on subsequent employment or employment plans. Nevertheless, the indirect effects of fertility plans are quite important, and it is ironic indeed that in static models employment plans—rather than fertility plans—seem to be the driving force.

---

[27] Admittedly, this may be due partly to poor measurement.

Because of the focus on the causal relationship between fertility and wife's employment, results for other variables have been discussed relatively briefly—and only to determine the adequacy of the data and models. Some of these results are substantively interesting, and it is worthwhile to summarize them here. The major theoretical basis for the models is the "new home economics," in which economic factors are presumed to be important determinants of household allocative decisions. The models of wife's employment before birth generally conform to economic expectations. The model of fertility status from 1968 to 1973 (in which timing considerations are minimized) also generally conforms to economic theories. Husband's economic resources stimulated fertility, while all three proxies for costs—wife's employment and potential wage rate, and age of youngest child—depressed fertility. Results from this model also support most of Hout's (1978) hypotheses about differences by parity. Other hypotheses about interaction effects proposed by Stolzenberg and Waite (1977), Willis (1973), and others were not supported, although the tests were not elegant or decisive.

The general drift toward dynamic models of fertility that characterizes recent research seems to be well advised. The static models estimated here are technically deficient and generally not very informative. Sequences of decisions about fertility and employment are influenced by such factors as economic incentives and pressures, but it seems unlikely that the sequences can be usefully summarized in terms of final outcomes and initial characteristics. Some contingencies, such as timing decisions associated with age and open interval, may be essentially random and can safely be averaged-out in static models. Other contingencies depend on aggregate historical trends and cycles, parity, and expected family size, and these cannot be understood in a static framework. Hout's explanations of interaction effects due to parity actually depend upon comparisons of parity with both social norms and individual fertility preferences, so these interactions are a specific example of contingencies that are best understood in dynamic models.

The case for dynamic models is weakened by at least three structural deficiencies in the present models (other, more specific, deficiencies will be noted later). First, the models incorporate fertility expectations only at middle and late stages of family formation. Information on the determinants of initial expectations and early changes in expectations is needed for a complete comparison of static and dynamic models. Second, our models treat households mainly in isolation. The only clear link to society is county demand for female labor, and this link is inadequate. Finally, it is unclear whether historical changes are endogenous or exogenous to the models. For example, aggregate changes in the timing of births were considered exogenous constraints in the anlaysis of Table 7, but with data on individuals' perceptions of business cycles and short-term economic prospects, the dynamic models should explain decisions about the timing of births. Clearly, the problem of relating aggregate trends and cycles with individual life cycle dynamics is related to the broader problem of linking household to society (Nerlove, 1974).

The discussion of fertility and female employment has been used to illustrate several methodological problems or issues. The methodological lessons certainly are not original, and sometimes are pretty mundane (for example, measuring income correctly), yet they seem often to be overlooked or poorly understood. Three general points have been illustrated.

(1) Nonrecursive models are not cheap devices for easily determining causal direction. The main problem, aside from specifying all relevant variables (a problem in all models), is weak instrumental variables, or multicollinearity. This is a common problem, because strong predictors are likely to directly affect both endogenous variables, especially in static models. The theoretical challenge of identifying instrumental variables is matched, especially with microlevel data, by the empirical problem of finding good instruments. If instruments are weak, the

"medicine" of 2SLS may be worse than the "disease" of unclear causal direction.

(2) Many research reports conclude with an expression of hope that dynamic (especially panel) models can solve problems of causal direction. This may be true, but dynamic models have their own inherent problems. Many of these problems involve time intervals. Problems encountered in the present research include the lag time between initial employment and fertility (compounded by measures defined over intervals, not at points in time, with the hazard of reciprocal effects from pregnancy to initial employment), when to measure consequences of fertility, and the length of the panel period (that is, the problem of time truncation). The latter problem was partially solved by studying behavioral sequences instead of time intervals, but this may not always be possible or appropriate.

(3) Historical trends and cycles may impinge significantly on dynamic models of individual behavior. For example, the relationship between fertility and employment may vary over the business cycle. Consideration of historical changes almost invariably creates problems of distinguishing among age, period, and cohort effects. The comparison of Tables 5 and 7 emphasized age and period effects, but the two samples also differ significantly with respect to cohort composition so the interpretation of Table 7 may be incorrect.

The discussion of methodological "lessons" is not intended to imply that the present research is exemplary. In fact, there are rather serious faults, and these will be mentioned briefly to indicate directions for future research. The most obvious problem is the specification of variables. Fertility and employment plans and intentions (including timing preferences) need to be measured much more carefully and extensively. A number of potentially important variables are missing from the present models: sex role attitudes, age at marriage, paid child care and family help, wife's commute time and other "costs" of employment, relative income, and child-rearing attitudes and practices are clear candidates. Equally obvious problems are the numerous simplifying assumptions that have been made in order to estimate and interpret the dynamic models. The major statistical and mathematical issues associated with dynamic models are complex and not yet fully understood (Blalock, 1969; Coleman, 1968; Cook and Campbell, 1979; Hannan and Young, 1977; Hibbs, 1974; Johnston, 1972: 379–80; Wheaton et al., 1977), but it is clear that they are at least as challenging as the problems with static nonrecursive models.

MANUSCRIPTS FOR THE
ASA ROSE SOCIOLOGY SERIES

Manuscripts (100 to 300 typed pages) are solicited for publication in the *ASA Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Suzanne Keller, Department of Sociology, Princeton University, Princeton, NJ 08540.

POLITICAL PROTEST ORIENTATIONS AMONG BLACK AND WHITE ADULTS*

SHELDON STRYKER
Indiana University

American Sociological Review 1980, Vol. 45 (April):191–213

The political protest activities of the late 1960s and early 1970s stimulated a flurry of empirical research by social scientists seeking explanations. Most of the research, aimed at explaining individuals' radical political orientations, willingness to use protest and perhaps violence, or actual riot or protest participation, has been guided by either a mass society perspective or some variant of the relative deprivation model. After outlining the basic elements of these two theories as well as an alternative differential socialization theory, central causal features of each theory are integrated into a structural equation model designed to explain individual political protest orientation, and the model (allowing for measurement error in the endogenous constructs) is estimated on separate samples of white and black adults. The results indicate strong race-specific differences in the formation of political orientations. Explanations for these differences are examined; the empirical patterns are interpreted as supporting a theory of differential political socialization.

INTRODUCTION

The widespread protest activity and collective violence of the 1960s and early 1970s,[1] outgrowths of the civil rights and antiwar movements, stimulated considerable research into the "preconditions, causes, dynamics, efforts to control and political significance of disorder" (Snyder and Kelly, 1979:1). Much of this research was guided (either explicitly or implicitly) by one of two relatively longstanding explanations for protest orientations and activity: a mass society explanation emphasizing political primitivism and isolation, or some variant of the relative deprivation argument predicated on a psychological frustration-aggression paradigm (see Useem, 1975, for cogent overviews). Particular versions of these arguments have received research attention at both aggregate and individual levels of analysis. The focus here is at the individual level, consistent with recent arguments concerning the appropriate level of analysis in examining various theories of collective political protest (see, especially, Snyder, 1978).

There is an alternative view of protest orientation and participation processes,[2] arguing the significance of differential political socialization (Portes, 1971a; 1971b)[3] and seeing protest orientations as

The ordering of authors is alphabetical. This research was partially supported by United States Public Health Service Grants MH 16939 and MH 14660. Thanks are due George Bohrnstedt, Peter Burke, Larry Griffin, Lowell Hargens, Elton Jackson, William Kelly, Robert Parker, Alejandro Portes, David Snyder, John Zipp and anonymous referees for helpful comments on drafts of this paper.

[1] Snyder and Kelly (1979) cite their U.S. city-level data as well as Spilerman's (1970) as evidence for the unprecedented nature of racial violence during this period.

[2] There are, of course, additional alternative views; for example, the more purely "political model" that focuses on variables such as political efficacy, trust, etc. (see Gamson, 1968). We think this political model overlaps with what we here refer to as the differential political socialization perspective. However, we do not deal directly in our analysis with this particular alternative.

[3] The assembling process framework developed by McPhail and Miller (1973) might be considered as a behavioral analogue to the differential political socialization framework, since the former stresses the flow of information, social density and other proximate features of context which either facilitate or impede the assemblage of persons in time and space.

the product of a complex learning process tied to social structure. This view does not necessarily see relative deprivation or isolation/integration as unimportant; they may well be aspects of the protest orientation formation process, but are likely to have varying effects in subgroups differently located in the social structure.

To examine components of these theoretical perspectives, we focus on individual level political protest orientations. Protest orientation is central to both the mass society and relative deprivation explanations of protest activity: the causal imagery embedded in these perspectives typically takes some version of protest orientation ("political radicalization," "politicalized discontent," "potential for political violence," etc.) as antecedent to actual behavioral or participation dimensions (Useem, 1975). In a sense, then, we provide a partial (but central) test of the traditional arguments. Whatever the direct relation of orientation to activity, however, protest orientation is important to understand because widespread approval of protest and violence as means to political ends creates a climate of support (and actual support) for the use of protest and violence. The relevance and implications of focusing on protest orientations rather than actual protest involvement are elaborated later.

Research on protest orientations and behaviors has had persistent shortcomings: (a) hypotheses tested generally are not tied explicitly to theoretical framework; thus, basic underlying assumptions typically do not surface (see Portes, 1971a; 1971b for major exceptions); (b) measurement of central explanatory concepts such as relative deprivation often fit these concepts badly (cf., McPhail, 1971; Crosby, 1976); (c) most studies do not go beyond the examination of simple bivariate measures of association between theoretically important variables (see McPhail's, 1971, extensive review); (d) few researchers have compared the strength of crucial relationships, or specified how processes might operate differentially, in important subpopulations (e.g., blacks and whites, or middle-class and working-class students [but see Long's, 1977, comparison of black and white adolescents]); and (e) virtually none of the many investigations have attempted to elaborate models integrating central components from more than one theoretical perspective (see Portes and Ross, 1974, for an empirical exception; Korpi, 1974, and Orum, 1974, for theoretical exceptions). None among the various exceptions cited simultaneously avoids all of the shortcomings mentioned.

All are addressed, in varying degree, in this article. Specifically, we (1) juxtapose three major explanations for protest orientations: versions of the mass society, relative deprivation, and differential political socialization arguments; (2) develop and employ a more theoretically grounded measure of relative deprivation (based on labor market experience) than is typically used; and (3) integrate major lines of causal argument in a structural equation model that is estimated separately for a sample of urban white and black adults. We think this race-specific analysis is crucial; it allows us to examine expected differences in the influence of important variables by race anticipated by the differential political socialization perspective.

THEORETICAL OVERVIEW

This section contains a general review of the three perspectives noted. It also makes three important points: First, there are critical differences in assumptions and causal mechanisms suggested by each perspective; second, political orientation toward the use of protest and collective violence is a central construct in the perspectives; third, while the mass society and relative deprivation perspectives tend to predict common effects of central causal variables in any subgroup in a population, the differential socialization approach is capable of accounting for differences between subgroups.

1. Mass Society

A number of variants of mass society theory (Kornhauser, 1959; Lipset, 1963; Fromm, 1963; Hoffer, 1966; Gusfield, 1962) exist which have several common features. All are concerned with "political extremism," a tendency to antidemocratic politics. Since compromise and a gradualist view of change are cornerstones of democratic politics, individuals who harbor favorable attitudes toward violence or indeed participate in protest or violent demonstrations are by definition extremists.

The making-of-the-extremist is seen to be due to special features of social life, particularly in the lower classes of mass societies.[4] "Political primitivism" (Portes, 1971a) is presumably produced by the lack of education and general information characteristic of the lower classes, and political primitives are expected to be prone to extremism (Lipset, 1963: chap. 4).

Social isolation, taken as characteristic of the lower-class social situation as well as a basic feature of mass societies, also presumably contributes to an extremist orientation toward politics (Gusfield, 1962:23). Thus, primary group integration and secondary association participation are central features in mass society theory's causal scheme. Primary group instability and consequent social isolation among the lower classes are sources of a lack of integration into the larger social order, as is the relative lack of secondary association participation (participation in schools, community organizations, etc.) through which the tenets of the democratic political process are thought to be learned.

The political imagery of mass society theory is linked to pluralist theory as its obverse; that is, extremism is viewed as an irrational political form within a rational political structure (Gusfield, 1962; Gamson, 1975). From this view, political orientations and actions are simplistic, do not reflect concrete socioeconomic interests, and derive from a particular irrational social psychology inherent in mass society (Portes, 1971a).

The mass society thesis thus translates into four hypotheses specifying conditions leading to political extremism: (1) primitivism (i.e., lack of education and general information), (2) structural and normative isolation of groups,[5] (3) individual isolation and detachment from secondary associations, and (4) individual isolation and detachment from primary groups.

Empirical work has found little support for the primitivism hypotheses (cf., Flacks, 1967; Marx, 1967; Paige, 1971; Portes, 1971a; 1971b).[6] The primary group integration hypothesis has received the least attention of all the basic mass society hypotheses. Moreover, what evidence does exist is not systematic enough to allow an informed judgment (but see Warren, 1970; Gerlach and Hine, 1970; Portes, 1971a; Pinard, 1971; Orum, 1972; Oberschall, 1973; Woelfel et al., 1974; Marx and Wood, 1975; Wilson and Orum, 1976, for predominantly negative evidence and theoretical arguments contrary to the mass society position). Our anlaysis bears on these two mass society hypotheses.

2. *Relative Deprivation*

Probably the most common explanation for the racial protest and radicalization of the black population during the 1960s and early 1970s is some version of the relative deprivation argument (e.g., National Advisory Commission's report on civil disorders, 1968). Typically, the gap between individuals' expectations and achievement on some value is posited as the primary force moving individuals to radical political orientations and activating participation in protest activities (e.g., Feierabend and Feierabend, 1966; Geschwender and Geschwender; 1973; Grofman and Muller, 1973; Gurr, 1970; Sears and McConahay, 1970).

---

[4] A fear of the lower classes is a central feature of the "elitist" view of the revolutionary crowd in history in which mass society theory has its roots. For a succinct overview of the images of the crowd and general theoretical frameworks embedded in the historical writing of the French Revolution, see Tilly (1964).

[5] This is the collective counterpart to individual isolation, also identifiable in the mass society literature (e.g., Kerr and Siegel, 1954). However, we do not deal with this particular version of the argument.

[6] Interestingly enough, the "primitivism" notion of the mass politics literature predicts the same negative effect of various dimensions of socioeconomic position (e.g., education, occupation, income) on political extremist orientations and actions as do absolute deprivation arguments (see, e.g., Caplan, 1970). They differ, however, in the interpretation of the processes thought to produce such effects.

Most empirical studies do not conceptualize the relationship of the perception or objective indication of what one has relative to what one thinks one should have as the primary causal variable in relating an expectations-achievement gap to radical political orientations. Rather, the inferred psychological force of frustration-anger[7] intervenes to produce the outcome. This suggests that the subjective evaluation of any perceived gap is central to political radicalization.

A large number of studies have tried to assess various forms of the relative deprivation argument. In general, these studies provide little convincing evidence of the impact of relative deprivation on protest orientations (see Muller, 1972; Grofman and Muller, 1973), individual protest participation (see McPhail, 1971, for a review) or protest/riot incidence in ecological units (see Snyder, 1978, for a review). Apart from theoretically based doubts concerning the centrality of relative deprivation in explaining collective violence incidence (e.g., Snyder and Tilly, 1972) or participation (e.g., McPhail, 1971), there are methodological grounds for remaining unconvinced by extant research. Specifically, these studies are plagued by two fundamental analytical problems beyond the fact that typically only bivariate relationships are examined (McPhail, 1971).

First, measures of relative deprivation bear only weak or partial resemblance to theoretical statements. The most pervasive measurement problem is that relative deprivation indicators typically do not assess anything beyond a perceptual difference in standing on some dimension of well-being (e.g., occupation, income, housing, etc.) thought to be important (e.g., Crawford and Naditch, 1970; Muller, 1972; Grofman and Muller, 1973; Geschwender and Geschwender, 1973). Such measures assume that perceived differences are synonymous with the deprivation-frustration-aggression model upon which they are based. There is, however, no reason to assume a priori that a perceived difference is a source of frustration or anger, much less an antecedent to radical political orientations or aggression (see also McPhail, 1971:1063). A sound measure of relative deprivation should include not only a value and comparison standard (Geschwender and Geschwender, 1973:404), but also the respondent's feeling-state toward the differential (cf., Morrison, 1973:153 for a similar but less explicit view).[8] In the analysis presented later, measures of relative deprivation are operationalized in precisely this way.

Second, there is the pervasive problem of treating societies as monoliths in aggregate level studies (Miller et al., 1977), or assuming constant relative deprivation effects across important subgroups in individual level studies.[9] Not only can aggregate data conceal important group differences, but individual level studies which lump together important subgroups (e.g., blacks and whites) may also mislead by assuming that relative deprivation is translated into political orientations in the same way in those subgroups. This is obviously a highly questionable assumption[10] which should be empirically examined.

3. *Differential Socialization*

Noting a consistent lack of support for the primitivism and isolation hypotheses of mass society theory in explaining leftist radical political orientations in a sample of urban slum-dwellers in Chile, Portes (1971a:829) points to four assumptions of that theory which his findings contradict: that leftist radicalism is (1) a simplistic political response, (2) an irrational orientation, (3) an abnormal or deviant process of attitude formation, and (4) a reactive formation process.

---

[7] Rather than a primitive frustration-anger response, an injustice-indignation response is probably more appropriate conceptually (see Lupsha, 1971).

[8] Nagel's (1974) argument is consistent with ours. His measure, however, is formulated at the aggregate level and so is unable to adequately capture the logic he so painstakingly puts forth.

[9] Even in individual level studies few group comparisons can be found. For a comparison of black and white adolescents, see Long (1977); for a comparison of race-region-specific results, see Miller et al. (1977); and for a comparison of males and females, see Orum and Orum (1968).

[10] Theoretical justification for this doubt is presented in the following section.

As an alternative interpretation of his data, Portes argues that leftist radicalism emerges within the context of a normal, complex attitude formation or learning process, "a period of intellectual apprenticeship" (Portes, 1971a:829) in which the personal problems of living in a lower-class situation come to be seen within "the general interpretative framework of a coherent theory of classes, class-interests, and class conflict" (Portes, 1971a:829).[11] This alternative suggests that differential socialization is the source of leftist radicalism. Leftist radicalism is seen as the outcome of exposure to a structurally oriented political ideology learned over a period of time through a variety of interactional or information sources—for example, from parents and peers, or through referent others in occupational or neighborhood milieux who have learned such orientations.[12] The differential socialization model thus relies on processes of interaction and information flow to explain radical political orientations, rather than relying on an "abnormal" explanation which sees this outcome as a response to precisely the opposite set of conditions (the lack of information, detachment, and isolation).

Contrary to the more orthodox perspectives, radical political orientations and protest participation are viewed as predominantly rational by this perspective. Embedded in a primary group structure, identified with persons—family, friends, neighbors—in that structure, protesters seek to advance the interests of self and others who compose that structure (see Wilson and Orum, 1976, for a relevant discussion). In this sense, the differential socialization view converges with emerging resource mobilization perspectives (cf., Tilly, 1978; Oberschall, 1973; Gamson, 1975), and may be useful in augmenting the individual interest component of mobilization models.[13]

The differential socialization perspective has still other implications worth noting. It leads us to view broad structural positions (e.g., race and class) as operating through interactional and "definitional" processes to affect political orientations and behaviors. It suggests that the impact of other influences on protest orientations and behavior—relative deprivation, for one—will vary with the "embeddedness" of people in group structures and the interests of those groups. It thus leads us to expect the varying import of such influences in different subgroups of a population. While the orthodox perspectives—mass society and relative deprivation—predict basically identical influences of forces such as isolation or relative deprivation throughout a population, the differential socialization argument does not. Beginning with this framework, we find that there are sound structural reasons for expecting the formation of protest orientations to vary by race,[14] reasons resting on important aspects of the political economy of race in American society.

---

[11] "Normal," here, should not be confused with prevalent. While the formulation of such political orientations may be said to occur through a normal learning process, the likelihood of learning abstract interpretive frameworks which link concrete working-class experience to a coherent theory of classes, etc., is not great. Mann (1970:437) suggests the explanation for this rather rare occurrence rests in the performance of dominant institutions (e.g., schools): "What has been ignored in childhood is unlikely to be grasped in adulthood, given working class difficulties with abstract concepts."

[12] There are, of course, other agents or institutions of political socialization. One which has received considerable attention is the school system. Such studies have typically concluded that schools (at least in the U.S. and Britain) are channels of political conservatism, especially in the case of working-class students (Mann, 1970). On the learning of deviant or radical political orientations, Mann (p. 436) states: "Presumably the working class child learns the latter from his *family* or *peers*; certainly he experiences something of the former when he enters the world of work, . . ." (emphasis added).

On the efficacy of schooling and work experience for children and adults respectively, see Orum (1976). However, Mann does note (p. 436, footnote 6) that there is conflicting evidence on the impact of the family in particular. There is evidence to suggest the "liberalizing" influence of the qualitative dimension of colleges in the U.S. (e.g., Knoke and Isaac, 1976). However, this finding does not refer to political means that might be employed in effecting change (our focus here) or on more radical political orientations concerning fundamental economic and political institutions (e.g., as in Portes, 1971a).

[13] It has become increasingly apparent that individual level processes need to be considered to fully explain protest, insurgency and collective violence (see, e.g., Snyder, 1978). While it is beyond the scope of this paper to develop, it is worth suggesting that this differential socialization approach may provide a logical individual level extension of the more organizationally oriented resource mobilization perspective.

Political economy of race and differential socializations. Race is obviously a highly salient ascribed status in American society, one which has been shown to be relevant in other areas of socialization (e.g., Porter, 1974, on educational and occupational attainment processes). Important racial differences have been shown in protest attitudes and participation, with blacks viewing protest consistently more favorably than whites (Eisinger, 1974).[15] Yet detailed arguments suggesting why we should expect such interactions by race in the formation of protest orientations have not been adequately spelled out.

There are several strong economic reasons for expecting the socialization process to differ by race; these ought to be mentioned but need not be rehearsed at length. Most simply stated, blacks have not done well in American society economically, whether measured absolutely or in human capital terms—i.e., relative to "investment." In the late 1960s, significant inequalities between whites and blacks remained on virtually every major dimension of material well-being: education, employment, income, wealth, etc. (e.g., see Franklin and Resnick, 1973; Farley, 1977; Jhabvala, 1977). Too, underlying labor market experiences have a basically dualistic structure, with economic institutions playing an important part in allocating blacks differentially into relatively disadvantaged sectors (e.g., see Baron and Hymer, 1977, on the Chicago labor market). More generally, race historically has been a major source of labor market segmentation in the United States (Edwards et al., 1975). And, of course, the labor market experience of many blacks has frequently been transitory and subject to repeated interruptions.

The civil rights movement did little to alter racially based economic inequalities, but did change political conditions considerably (Piven and Cloward, 1977). The post-World War II period undoubtedly saw an increased perception of political efficacy among blacks, both in terms of protest and institutionalized politics. There is evidence, for example, that welfare purses and rolls expanded nationally as a function of black political disorder (Piven and Cloward, 1971; Isaac and Kelly, 1979). There is also evidence of increased participation in more conventional or institutionalized politics (Danigelis, 1978), perhaps spilling over from the heightened sense of insurgent-based political efficacy.[16] It is these basic changes in the political climate for blacks, together with the relatively unchanged economic circumstances, which provide the grounds for expecting the political orientation formation process to differ by race.

Changes in the political climate of the sort noted here probably interacted with economic inequalities and labor market experiences to alter definitions of longstanding human capital problems among blacks. The argument previously made concerning relative deprivation is that the conceptualization of that phenomenon must go beyond an objective or perceived gap to the definition of that gap in negative terms that leads to frustration and anger. Those who experience labor market-based deprivations and learn to interpret them structurally or as the responsibility of the system—and integration into webs of affiliation facilitates this learning—are more likely to define the gap negatively, to become frustrated by and angry about it, and subsequently to develop radical political protest orientations. The civil rights and the welfare rights movement provided black Americans with the opportunity for learning "appropriate" political interpretations. Working-class or poor whites may have experienced similar labor market problems, but lacked the interactional base for this political learning process.

---

[14] It would, of course, be possible to present compelling theoretical reasons for expecting different processes within class categories. Given the lines along which protesters were mobilized in the late 1960s and early 1970s, comparing the processes by race is an important first step.

[15] Eisinger's (1974) results are based on survey data similar to ours taken from Milwaukee in 1970.

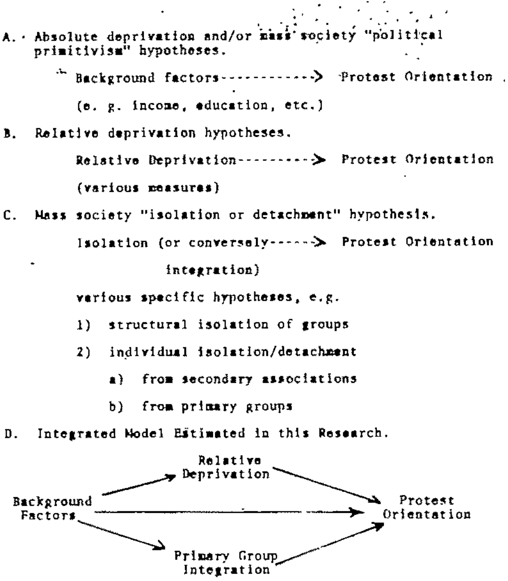
[16] The gap in black-white institutionalized political participation reversed after 1960 and the peak for blacks occurred over the 1964–1968 period for both North and South (Danigelis, 1978). This was also the peak of racial disturbance frequency and severity (Isaac and Kelly, 1979).

THE GENERIC MODELS

Prior attempts to evaluate the central hypotheses of one or the other of the theories reviewed as they may apply to the formation of protest orientations or to actual protest participation have not integrated hypothesized causal factors into a single model. By failing to do so, the risk is run of interpreting spurious relationships, as is the risk of misreading the evidence concerning alternative theoretical explanations. We want to motivate a simple generic causal model which subsequently can be more elaborately specified and estimated. The value in doing so is that several of the central alternative predictions of competing explanations can then be evaluated simultaneously.

Figures 1-A through 1-C represent the generic models underlying the components of mass society and relative deprivation theory on which we focus.

Figure 1-D represents a simplified generic version of the model which we will subsequently estimate. This model incorporates central causal components of the mass society,[17] relative deprivation and differential socialization arguments outlined. Individuals' background characteristics are taken to be reasonable indicators of location in the social structure. The ultimate (endogenous) variable of interest is political protest orientation. We consider relative deprivation and primary group integration as intervening between the background factors and protest orientation. While it would be possible to develop causal arguments concerning the relationship between relative deprivation and primary group integration, this is not the focus of our analysis, and we leave the relationship between these intervening constructs unanalyzed. Both intervening constructs and protest orientations are taken to be partial functions of social structural position.[18]



A. Absolute deprivation and/or mass society "political primitivism" hypotheses.
Background factors----------> Protest Orientation
(e. g. income, education, etc.)
B. Relative deprivation hypotheses.
Relative Deprivation---------> Protest Orientation
(various measures)
C. Mass society "isolation or detachment" hypothesis.
Isolation (or conversely-----> Protest Orientation
integration)
various specific hypotheses, e.g.
1) structural isolation of groups
2) individual isolation/detachment
a) from secondary associations
b) from primary groups
D. Integrated Model Estimated in this Research.
Relative Deprivation
Background Factors
Protest Orientation
Primary Group Integration

DATA AND METHODS

The Sample

Our data come from a survey directed by one of the authors (Stryker), focusing on political attitudes and orientations, carried out as the 1969 Gary Area Project of the Institute of Social Research at Indiana University. Interviews were conducted during January, 1969, by trained graduate students and professional interviewers. The survey employed probability sampling of blocks (and block clusters), relying on quota sampling of individuals within blocks (a procedure much like that used by NORC).[19] The final sample consisted of 800 adult residents of Gary, Indiana, including 432 whites and 357 blacks. Eliminating all respondents for whom there were missing data on any of the variables in our model resulted in a useable sample, for the present analysis, of 247 white and 204 black adults. Tests employed to determine whether deleted cases (those with missing data) were different from those retained, with respect to the dependent protest orientation variable, revealed no significant difference for either racial group (see Cohen and Cohen, 1975, for further discussion of the procedure).[20]

---

[17] The mass society hypothesis (other than the primitivism argument) for which we have data and that would logically fit into the integrated model is the primary group isolation/detachment hypothesis.

[18] In fact, as repeatedly noted, we see relative deprivation as arising from more than structural position alone. It should arise from structural positions that place one in a position of being differentially treated due to ascribed characteristics; the actual difference must be perceived, and once perceived must be evaluated negatively, and not interpreted as an individual shortcoming. The negative evaluation is most problematic, involving learning to interpret the differential within a structural or power difference framework as opposed to an individual responsibility-failure framework. For previous related work which emphasizes the importance of learning structural blame, see Portes (1971a; 1971b) and Portes and Ross (1974).

[19] In this procedure, quotas are established, based on the probabilities of particular kinds of persons not

Several aspects of the political history of the site of data collection are important. Gary was founded in 1906 by the United States Steel Corporation and eventually became the largest company town in the United States. Since its founding, Gary has been the site of an extremely diverse ethnic-based political history (see Mohl and Betten, 1972). Gary was one of the first large United States cities to elect a black mayor (in 1967; see Starnes, 1973, for further detail), and also one of the important locations of black protest during the 1960s (see National Advisory Commission's report on civil disorders, 1968). These features of Gary's history should be borne in mind when considering the results and general theoretical implications of our analysis.

Variables

The variables in the analysis correspond generally to the four blocks shown in the full generic model (Figure 1-D). The number of variables, however, is substantially greater than four. Three measures of primary group integration are used, and there are multiple indicators for these constructs, as well as for relative deprivation and political protest orientations.

Exogenous variables.

Five exogenous variables are employed in this analysis; four are background status variables and one is a proxy for proximity to radical protest attitudes and information. These are: (1) *age*—the respondent's age (in years) on his/her most recent birthday; (2) *education*—indicated by a five-point item with attainment categories ranging from less than ninth grade to college graduate; (3) *income*—indicated by total family income before taxes in 1967, coded in $2,000 unit intervals and ranging from less than $2,000 to $16,000 or more that year;[21] (4) *occupational status*—indicated by the Duncan SEI; and (5) areal referent others (ARO)—an ecological proxy for referent others, dominant political protest orientations. Following Portes's (1971a; 1971b) early work, this is an attempt to get at the neighborhood political milieux in which our respondents operated, on the assumption that neighborhood settings represent socialization contexts of potential import. In the absence of data directly reflecting the political orientations of re-

---

being at home when an interviewer calls in order to compensate for these not-at-homes. Quotas were established for the variables—sex, age of males, and female employment status. Comparisons of sample distributions with 1960 and 1970 census distributions indicate that the sample provided disproportionately more blacks than were in Gary in 1960 and less than in 1970, as would be expected by shifts in residential patterns that occurred during this time interval. Other differences between sample and census distributions reflected the proportion of blacks in the sample. The refusal rate was approximately ten percent. All in all, the evidence is that the sample represented Gary reasonably well.

[20] Further, a comparison of the covariance matrix for those with complete information on all variables with the matrix derived from a pairwise estimation procedure was conducted, using an omnibus test for equality of matrices (Specht and Warren, 1976). This comparison was completed separately for each racial category and the matrices were found not to differ significantly. Consequently, we can conclude that the pattern of results would be substantially the same, regardless of which matrix is used. By basing the analysis on only those cases with complete information, we have the advantage that all estimates are based on consistent samples. Missing data are relatively equally scattered across the variables in the analysis. While these observations do not obviate the missing data problem, they do serve to mitigate it. It might be noted, in passing, that any accommodation to missing data has its own difficulties (Kim and Curry, 1977).

[21] This measure of family income, as scaled, is obviously truncated to some extent. We suspect that the restriction in income variance is likely to be more pronounced for whites than blacks. Therefore, income effects on any endogenous variable in the model are likely to be somewhat attenuated, and more so for the white than black results.

spondents' neighborhood contacts, we resorted to this ecological proxy. It was constructed by assigning a binary code to each respondent, dependent on whether she/he resided in a census tract that was below (0) or above (1) the grand mean on the political protest orientation construct.[22]

Relative deprivation. Consistent with our previous discussion of the measurement of relative deprivation, two relative deprivation indicators were constructed, both referring to labor market experiences: (1) *relative income deprivation* (RID) and (2) *relative occupational deprivation* (ROD). Each was constructed using a two-item conditional score to capture both a perceived differential and the degree of negative evaluation concerning that differential. One of the component items asked for the perceived income (occupational) differential using "most people with the same amount of education" as the reference group; and the other component concerned the degree to which the perceived differential bothered the respondent.[23] In the models to be estimated below, the two measures—RID and ROD—are taken as observable indicators of a general labor market experiences *relative deprivation* construct.

Primary group integration. Three unmeasured constructs are used as measures of primary group integration: (1) *friends' integration* (Fr.I.), (2) *family integration* (Fam.I.), and (3) *neighborhood integration* (N.I.). Each construct is indicated by four observable items which have been scaled to equal intervals ranging from zero to one.[24]

Political protest orientation. The endogenous construct of primary interest is political protest orientation (PO). Protest orientation is also treated as an unmeasured variable indicated by six observable variables dealing with various types of collective protest or political insurgent action the respondent feels are appropriate for members of dissatisfied groups to employ. It is best conceived not as a construct of actual protest involvement or of explicit intention to become involved in such action, but a construct of approval of protest and insurgent politics as a legitimate means of attaining political goals.[25]

---

[22] At the time this research was conducted, Gary had twenty-seven census tracts. No sample blocks were drawn in one of them, a tract which contained 327 households. All remaining tracts, with households numbering from 966 to 4,560, were the source of at least two sample clusters of ten respondents each, with the maximum being seventy. Thus, at minimum, the areal referent other measure was based on the responses of twenty persons: 44% of the respondents lived in tracts (N=14) below the mean, 56% in tracts (N=12) above the mean. This measure correlates strongly (above .90) with a measure omitting respondents' own scores. We dichotomized this measure in order to place the individual in a social context and to avoid the assumption of a linear relationship between individuals' attitudes and those of the neighborhood in which they live.

[23] Specifically, the relative deprivation indicators were constructed as follows: Relative income (R.I.)—"Think now of people who have about as much education as you have (your husband has), do you think that most people with that amount of education have—much higher incomes (0), somewhat higher incomes (1), about the same income (2), or somewhat or much lower incomes (3)?" Perceived deprivation (P.D.)—"Does this bother you—not at all (2), somewhat (1), or very much (0)?" If relative income (R.I.) equals 1 or 0 and perceived deprivation (P.D.) equals 0, then relative income deprivation (R.I.D.) equals 3. If R.I. equals 1 or 0 and P.D. equals 1, then R.I.D. equals 2. If R.I. equals 1 or 0 and P.D. equals 2, then R.I.D. equals 1. If R.I. equals 2 or 3, then R.I.D. equals 0. The relative occupational deprivation indicator was constructed in precisely the same manner, with the item content referring to the job instead of income.

[24] The indicators for the primary group integration constructs are: (A) *Integration with friends* (Fr. I.)—(1) When I am with friends I can just be myself, (2) When I talk to my friends I get nervous (reverse coded), (3) My friends don't appreciate the things I do for them (reverse coded), (4) I can count on my friends (all items, 0=never, .33=seldom, .67=often, 1=always). (B) *Family integration* (Fam. I.)—(1) My family makes me nervous (reverse coded), (2) I can act the way I want when I am with my family, (3) All things considered, I get a lot of satisfaction from my family, (4) For any problem I can count on my family for help (all items, 0=never, .33=seldom, .67=often, 1=always). (C) *Neighborhood integration* (N.I.)—(1) Do your neighbors ask you for information or discuss things with you? (2) Whenever people in the neighborhood get together to get something done, do you take an active part? (both items, 0=never, .33=seldom, .67=often, 1=always). (3) People have different ideas of how they themselves fit into their neighborhood. How would you say you fit into this neighborhood? Are you a person who: is not really a part of this neighborhood at all (0); is just an ordinary neighborhood member (.33); is active but not one of the decision makers (.67); contributes to neighborhood decisions (1)? (4) On the average how many times per week do you talk with any of your neighbors? Don't talk with any (0); less than once a week (.2); once or twice a week (.4); three-four times a week (.6); five-six times a week (.8); every day or more (1.0)?

Although direct measures of participation in protest activities as well would be highly desirable, a focus on the formation of political orientations as conceptualized is important for several reasons. First, while the surmise is untested here, it is likely that such orientations dispose individuals to participate or not participate, at least to some degree. Second, as suggested earlier, such orientations are important in their own right to the extent that they reflect potential for "third party" support in the form of "public opinion." Third, as also suggested earlier, such "radical" orientations are embedded (to varying degrees) in the major perspectives which we are proposing to test in this analysis. Finally, these general orientations toward protest and insurgent politics bear on a more general question assumed in most treatments of pluralist political theory: the degree of political procedural consensus (in this case, "dissensus"). The process by which persons (and subgroups) form political orientations antithetical to a fundamental premise of a major view of United States politics is certainly worthy of attention.

The individual items in the PO measure refer to the appropriateness of employing the following forms of social protest: (a) "sit-in" and "walk-outs," (b) mass demonstrations, (c) civil disobedience, (d) use of violence to attain goals for minorities in general, (e) use of violent versus nonviolent politics for blacks in particular, and (f) the extent to which civil disobedience is a method to disrupt and destroy our society (reverse coded). As with the primary group integration measures described previously, all variables have been scaled so that the response range is in equal intervals from zero to one. What is unique about our treatment of protest orientations is that we specify them as indicators of an unmeasured construct, which (a) allows explicit introduction of the measurement structure while not presuming the items to be perfect (no measurement error) measures of the construct of interest, and (b) allows the examination of effects of antecedent variables on particular attitudinal items separately (hence we need not assume that all items are affected homogeneously as with the use of traditional composite indexes).

Model Specification and Estimation

The basic model to be estimated derives from our earlier theoretical explication and parallels the generic model shown in Figure 1-D. Verbally, the system contains five equations in which relative deprivation (RD), the three primary groups' integration constructs (Fr.I., Fam. I., N.I.) are all taken to be functions of the five exogenous variables (AGE, ED, INC, OCC, and ARO), but not causally related to each other (however, we do allow these four intervening constructs to be related through their error structure);[26] and the protest orientation (PO) construct is also taken to be dependent on all five exogenous variables plus the four intervening constructs. Symbolically, the system is as follows:

$$\text{RD} = \gamma_{11}\,\text{AGE} + \gamma_{12}\,\text{ED} + \gamma_{13}\,\text{INC} + \gamma_{14}\,\text{OCC} + \gamma_{15}\,\text{ARO} + \zeta_1 \qquad (1)$$

$$\text{Fr.I.} = \gamma_{21}\,\text{AGE} + \ldots + \ldots + \ldots + \gamma_{25}\,\text{ARO} + \zeta_2 \qquad (2)$$

$$\text{Fam.I.} = \gamma_{31}\,\text{AGE} + \ldots + \ldots + \ldots + \gamma_{35}\,\text{ARO} + \zeta_3 \qquad (3)$$

$$\text{N.I.} = \gamma_{41}\,\text{AGE} + \ldots + \ldots + \ldots + \gamma_{45}\,\text{ARO} + \gamma_4 \qquad (4)$$

---

[25] Others have employed similar attitudinal measures but usually in a composite scale. Probably most similar to our construct is the Potential for Political Violence (PPV) scale developed by Muller (1972) and also employed by Grofman and Muller (1973). Portes's (1971a; 1971b) scale is, in content, much more a measure of left-wing political orientations than our measure. See Fendrich (1977) for a different, but similar, left-wing political attitude scale.

[26] It is worth mentioning at this point that a number of alternative specifications were examined (in particular, we allowed recursive causal relations between the intervening constructs and also estimated the system by fixing the measurement structure a priori. The resulting estimations fail to alter in any meaningful sense the major patterns and conclusions observed below.

$$PO = \gamma_{51}\ AGE + \ldots + \ldots + \ldots + \gamma_{55}\ ARO + B_{51}\ RD + B_{52}\ Fr.I. + B_{53}\ Fam.I. + B_{54}\ NI + \zeta_5. \quad (5)$$

Each of the constructs on the left-hand side of equations (1) through (5) is indicated by more than one observable variable, and thus implies a set of auxiliary or measurement equations embedded within the overall structural system. The parameters associated with the measurement structure are also estimated in the context of the overall model.[27]

Parameter estimates for the system of equations were obtained through the use of a full-information maximum likelihood program (Jöreskog and Sörbom, 1976). This program is well-suited for present purposes since it allows a simultaneous estimation of all model parameters, including the measurement structure and the correlated disturbances in the equations, as well as correlated measurement errors. The program also provides a test statistic for goodness-of-fit which, under the assumption of multivariate normality, is distributed as χ^2 with degrees of freedom equal to the number of overidentifying restrictions. Furthermore, this program provides information which may be useful in respecifying the estimated model.[28]

RESULTS

The analysis proceeds by estimating the model represented in Equations (1) through (5) separately for whites and blacks. Our expectation that the processes of interest would differ by race was initially borne out in a test of the heterogeneity between race-specific covariance matrices. Using the Box M test (see Specht and Warren, 1976), we obtained $\chi^2 = 584.024$, with 325 degrees of freedom and $Z = 7.63$, which led us to reject the null hypothesis of cross-race homogeneity of covariance structures. Tests for differences by sex produced no significant main or interaction effects.

The means, standard deviations and zero-order correlations for all variables specific to race are presented in the Appendix. We do not wish to dwell on these simple relationships. However, it is worth noting that the two observable relative deprivation measures (y_1 and y_2) are weakly, or at best modestly, correlated with the six observable protest measures (y_{15} to y_{20}). This is consistent with previous findings on such items (cf., e.g., McPhail, 1971; Long, 1977). When considering general construct effects (in effect incorporating measurement error, shown later), the findings become substantially more interesting.

White Sample

Table 1 presents the standardized and metric slopes as well as standard errors for the final model based on the white

---

[27] The measurement structure for the five unmeasured endogenous constructs is given by:

$$\begin{aligned}
y_1 &= \lambda_{11}\ RD + E_1\\
y_2 &= \lambda_{21}\ RD + E_2\\
\\
y_3 &= \lambda_{32}\ Fr.I + E_3\\
&\vdots\\
y_6 &= \lambda_{62}\ Fr.I + E_6\\
\\
y_7 &= \lambda_{73}\ Fam.I + E_7\\
&\vdots\\
y_{10} &= \lambda_{10.3}\ Fam.I. + E_{10}\\
\\
y_{11} &= \lambda_{11.4}\ N.I. + E_{11}\\
&\vdots\\
y_{14} &= \lambda_{14.4}\ N.I. + E_{14}\\
\\
y_{15} &= \lambda_{15.5}\ PO + E_{15}\\
&\vdots\\
y_{20} &= \lambda_{20.5}\ PO + E_{20}
\end{aligned}$$

where: y_1 = observed relative income deprivation; y_2 = observed relative occupational deprivation; y_3 to y_6 = observed measures of integration with friends (see fn. 24 for content and order); y_7 to y_{10} = observed measures of family integration (see fn. 24); y_{11} to y_{14} = observed measures of neighborhood integration (see fn. 24); and y_{15} to y_{20} = observed measures of protest orientation (see text).

[28] The program provides the first-order partial derivatives of the fitting function with respect to each of the parameters in the model, whether free or fixed. Examination of these derivative matrices for the element of largest absolute value may lead to useful respecification information if the parameter is identified and it makes theoretical sense to estimate it (see Sörbom, 1975, for a full discussion of the procedure). We do not, however, allow this information to dictate our theoretical argument. The information is employed only as an aid in determining when disturbances and measurement errors should be estimated, rather than assumed to be zero.

sample. In arriving at these results, we first estimated a version of the model which assumed all disturbance (in equations) and measurement error covariances to be zero. We then proceeded incrementally to relax these assumptions, where warranted, based on the partial derivatives of the fitting function with respect to the particular constrained parameters (see Sörbom, 1975). We especially expected correlated disturbances for the four intervening constructs since we specified no causal relationship among them. The process continued until freeing-up such covariances produced nonsignificant parameter estimates. (These estimated covariances are shown at the bottom of Figure 2.) This final model resulted in a very reasonable fit of the model to the data ($\chi^2 = 290.047$, df = 239, p = .01).[29]

We are predominantly concerned with the relative magnitude of coefficients within racial models, since the metrics of most of our variables have no inherent meaning.[30] Because of this, and also for convenience, the significant standardized effect parameters are presented in Figure 2.

Focusing first on the effects of the socioeconomic variables (education, income, and occupation) on protest orientation, we find support neither for the mass society "primitivism" hypothesis, nor for the relative deprivation thesis, since none of these coefficients departs significantly from zero. Contrary to the "primitivism" thesis, which predicts a negative education effect, a number of studies (e.g., Portes, 1971a) have reported relatively strong positive education effects on "leftist radicalism" and on other measures similar to ours.

On the other hand, there are several significant direct effects on the protest orientation construct. (All indirect effects are trivial.) Age, integration with friends and into the neighborhood all show moderately large, significant negative effects. The negative age effect is consistent with at least some findings on aging and political orientations (cf., Hendricks and Hendricks, 1977) and recent results concerning party preferences over the past two decades in the United States (see Knoke and Hout, 1974).[31] The negative effects of two of the three integration constructs (i.e., friends and neighborhood) are consistent with the mass society primary group isolation arguments. A more detailed and comparative alternative explanation is postponed until the concluding section of this article.

The only variable in the model which produces more "radical" protest orientations is the referent other proxy. Those residing in areas (census tracts) which are, in general, more "radical" also tend to be more radical in their acceptance or approval of noninstitutionalized political action, a result consistent with the differential socialization flow of information imagery. The primary group integration dimensions, however, play the major role in explaining protest orientations among whites; and they relate negatively (i.e., the higher the integration, the lower the protest orientations).

Black Sample

Table 2 shows the standardized and unstandardized parameter estimates as well

---

[29] The fit per degree of freedom (i.e., χ^2/df) is probably a better indication of overall fit (see Wheaton et al., 1977). The χ^2/df for this model is 1.2—substantially below the ratio of 5 suggested by Wheaton et al. as minimally reasonable.

[30] This is especially the case with the unmeasured variables in the model. In order to provide a metric for such variables some restriction must be made. We chose to follow the Jöreskog and Goldberger (1975) suggestion of fixing the error variance of each unmeasured construct in the model at 1.0. Other decisions which fix the metric of such unobserved variables are, of course, possible. For example, we also treated all primary group integration and the protest orientation constructs as composite scales and estimated the models with the epistemic coefficients fixed a priori based on internal consistency reliabilities. These results (not reported here) gave substantive conclusions consistent with those we have reported in the text.

[31] Knoke and Hout's (1974) study presents evidence for such a life-cycle or aging effect on party preferences; that is, net of period, cohort and other important determinants, age produces shifts away from the Democratic party to Republican and Independent alternatives. We cannot be so confident in interpreting the linear age effect in our results since we are unable to remove the potential confounding effects of cohort (see Mason et al., 1973). There are, of course, no period effects since observations were all taken at the same time.

as standard errors for the same model (with the exception of the error structure) based on the black sample. The fit of the model to the data ($\chi^2 = 270.322$, df = 238, p = .07), is quite reasonable.[32]

At this point, we are again most concerned with the within-sample relative magnitude of effects and therefore focus on the standardized estimates presented in Figure 3. Looking first at socioeconomic background variables, education has a sizable significant direct effect on protest orientations, contrary to our results for the white sample. As with the white results, however, this finding is contrary to the mass society "primitivism" hypothesis and is even stronger negative evidence than provided by the data for whites, since the effect is in the opposite direction to that predicted by the hypothesis. This positive direct education effect is also consistent with the findings of other studies from black samples (cf., Marx, 1967; Caplan and Paige, 1968; McCord and Howard, 1968; Tomlinson, 1970. See especially Caplan, 1970, for a more thorough review of empirical generalizations for blacks in the United States). And it is consistent with Portes's (1971a) findings for lower-class urban Chileans. Again, income and occupation play no direct role in influencing protest orientation.

A major departure from the pattern of results for whites is contained in the findings with respect to the primary group integration constructs. For the white sample, friends' integration and neighborhood integration had a "conservatizing" (negative) impact on protest orientation. For the black sample, family integration has a "conservatizing" influence, while integration with friends has a larger "radicalizing" influence. The difference between the direction of friends' and family influence is consistent with some findings on major institutional influence differences in the political socialization of lower-class persons—particularly the ambiguity surrounding the influence of the family (see Mann, 1970).

Again contrary to the results for whites is the substantial positive relative deprivation effect.[33] Blacks who perceive economic differentials between themselves and most others with equivalent education and who are bothered by these perceived differentials are significantly more inclined to positive views toward political protest. There is also, for blacks, some minimal support for the absolute deprivation argument in that income and occupation show negative indirect effects on protest orientation through relative deprivation.

Along with the positive effects already described, there is a strong positive effect of the referent others proxy, suggesting that the protest orientations of individuals are importantly affected by the political orientations of others living in close proximity to them.

These results, particularly the support for the relative deprivation hypothesis in the black sample, are unique in that no other study (to our knowledge) has produced such strong race-specific support for this hypothesis, net of other influences, and at the individual level. Overall, the pattern of race-specific effects suggests quite different pictures of the process by which political orientations develop in black and white populations. For whites, it is the young, those not integrated into friendship and neighborhood structures,

---

[32] The fit per degree of freedom, here, is 1.1, roughly the same as that reported for the white sample, in spite of the differences in probability levels associated with the two χ^2 tests (See fn. 29).

[33] As can be seen in comparing the epistemic coefficients for relative deprivation in the white (Figure 2) and black (Figure 3) models, the relative magnitude of the deprivation validity coefficients are not consistent for the two groups. For whites, the relative deprivation construct is predominantly given its meaning by the relative income deprivation variable ($\lambda = 1.000$), while for blacks, the relative occupational deprivation measure has the largest of the two validity coefficients ($\lambda = .828$). It is also the case that the meaning of an unmeasured variable can be a function of antecedent variables affecting it as well as its indicators (see Burt, 1976). Because we were concerned with the relative validities of the relative deprivation indicators and the fact that the relative deprivation construct was a function of different exogenous influences across samples, we estimated the model for blacks and whites, assuming that the relative deprivation indicators were perfectly measured. The results did not alter our substantive conclusions; for whites neither deprivation variable showed a significant effect on protest orientation and for blacks only relative occupational deprivation had a significant effect on protest orientation.

and those who live in parts of the city where close contacts are likely to hold similar favorable attitudes toward protest, who are most prone to view political protest and violence favorably. For blacks, it is those who harbor feelings of economic-induced relative deprivation, who have higher education, who are integrated into friendship structures but not integrated into the family, and who also live in parts of the city where close contacts are likely to hold similar favorable attitudes toward protest, who are most prone to view political protest and violence favorably. While the race-specific patterns show interesting differences, the one strong common determinant of protest orientation is the proximity of others who hold similar views.

DISCUSSION

There has been very little empirical analysis directed at the primary group isolation hypothesis of mass society theory. The findings of this study support Pinard's (1971) conclusion that the impact of primary group isolation (integration) is likely to depend on the social context and political orientation of particular primary groups. That conclusion, in turn, reinforces our sense that the proper interpretation of our findings with regard to the primary group integration variables is not that of mass society theory. Rather than the interpretation suggested by the mass society perspective (that isolation breeds a reactive formation), it seems much more reasonable to view the observed effects on protest orientation in differential political socialization terms: Those whites who have roots in a geographical area in the form of ties to family, friends and neighborhood networks with a stake in political stability learn a conservative orientation toward political protest; those blacks who have ties to other blacks who see the interests of blacks as requiring political changes through unconventional political means learn a more radical orientation. We will return to these conclusions.

With regard to another aspect of the mass society thesis, our data strongly suggest that "primitivism" (due to lack of education, information and appreciation for democratic principles) is not at the roots of individual leftist political orientations or mass movements in general. Our findings at this point add to an increasingly large body of negative evidence now accumulated. There is an important duality suggested in these results: For some groups educational attainment may lead to increased institutionalized political participation (e.g., voting); for other, perhaps more powerless, groups it may lead to noninstitutionalized political orientations and participation (e.g., protest).

As earlier noted, there has been little by way of empirical support for the relative deprivation hypothesis (see Caplan, 1970; McPhail, 1971 and Useem, 1975, for comprehensive reviews) when tested on individual level data. The reasonably strong net effect of relative deprivation on protest orientation for our black sample runs contrary to this evidence. It is possible that this finding is attributable to (1) our better measurement of the concept, and/or (2) the fact that we allow for measurement error in the estimation of the structural model. Either or both of these would better allow a "real" effect to appear. Only further research, however, will show whether this finding will replicate. In any event, this supportive evidence for relative deprivation must be tempered. Relative deprivation may indeed be a radicalizing experience for certain subpopulations in different times and places, but the importance of resource mobilization (Snyder and Tilly, 1972; Tilly, 1978; McCarthy and Zald, 1977) and the contingencies of the assembling process (McPhail and Miller, 1973) in the determination of actual collective protest and violence certainly should not be minimized.

Our finding of race-specific patterns can be best understood, we think, within a differential socialization framework (Portes, 1971a; 1971b). Both the white and black results for the primary group integration variables, and the black results for the relative deprivation variable make sense from this perspective. The negative signs on the coefficients relating the integration measures to the protest orientations measure suggest a "disidentification" (alienation) process for whites; the positive sign on the coefficients relating friends' integration to protest orientation for blacks suggests quite the opposite. One way of reading these results is to say that for whites, being "top-dog" in the racial system of the society, integration into the system through friends and neighborhood leads to a protective disinclination to endorse violence, to avoid political means which threaten the system. For blacks, being underdogs in the racial system, that integration leads to identification with the interests of blacks vis-à-vis whites and to an endorsement of violence as a means of shaking up the system.

This interpretation gains substance when one remembers the time of the data collection (January, 1969), a time when the country was extremely sensitized to the issues of racial conflict and violence. Furthermore, the site of the data collection (Gary, Indiana) had at this time a social environment in which race was a central politicized issue, given the political moves and eventual success of Richard Hatcher, its black mayor (see Starnes, 1973, for more detail on the political climate of Gary at this time).

The finding involving relative deprivation for the black sample enhances this socialization interpretation. Indeed, a socialization process is implicit in the very construction of our two relative deprivation indicators. As we argued earlier, the concept of relative deprivation is properly measured when it includes not only a perceived inequity but also a negative evaluative component. In other words, the inequity must be learned to be associated with structural sources rather than accounted for in terms of personal blame. Inequities are ubiquitous in time and space, but not all inequities create relative deprivation. In order for relative deprivation to occur (at least in its reference group form) individuals and groups must learn to look for the source of the inequity outside themselves—in a sense, they must serve a "period of intellectual apprenticeship. . . ." (Portes, 1971a:832)—which creates the feeling of anger or indignation surrounding the perceived inequity.[34] Inner city life in the late 1960s—the height of the black consciousness movement—provided such a learning experience for many blacks.

Our results derive from a cross-section of the black and white adult populations of a midwestern city of 1969. For some effects (e.g., education) there is a substantial amount of consistent evidence. However, for hypotheses concerning complex constructs such as relative deprivation, the consistency in the evidence is difficult to ascertain since measures employed and models estimated vary widely. In this regard, our results contradict, in several ways, aspects of two traditional perspectives and other empirical research. We hope others will attempt to refute these findings by examining similar or related questions for different temporal and spatial locations.

Finally, these race-specific findings suggest that the reasons for the development of unconventional political orientations differ according to structural location. Although there does not appear to be enormous debate over aggregate differences in protest orientations between blacks and whites (see, e.g., Eisinger, 1974), the process through which such orientations are formed is not well known. More generally, these results bear on one of the central components in the pluralist model of American politics, the notion of *procedural consensus* (cf. Mann, 1970; Gamson, 1975:chap. 1). Where procedural consensus does not exist (i.e., where established political procedure is disavowed), such a disavowal appears to be formed in different ways for different groups, and in ways which are theoretically comprehensible.

---

[34] It is quite possible that the relative deprivation effect observed in our analysis understates other more powerful aspects of the concept. Ours is an individualistic comparison measure and does not tap the total group dimension of relative deprivation—for example, blacks as compared to whites in general. Specifically, we have in mind the distinction between egoistic and fraternalistic forms of the concept (see Runciman, 1966; Vanneman and Pettigrew, 1972).

ERRATA

- An error occurred on page 708 in the article, "The Open and Closed Question" (ASR, October, 1979), by Howard Schuman and Stanley Presser.

In column one, the third sentence in the first full paragraph began: "As Table 7 shows, 99% of the . . . ." It should have begun: "As Table 7 shows, 98% of the . . . ."

- Errors occurred in Table 3 (page 921) of the article, "Inequality and Police Strength" (ASR, December, 1979), by David Jacobs.

First, in accord with Table 2, each of the four beta weights (.227*, .135, .213*, and .107) for the population variable ("Log Population") should move to the right, one column. Thus, coefficients for this variable should have appeared only in the columns under the headings, "Substantial Intercorrelations."

Second, the coefficient for the "% Black" variable in the fourth column from the left (.206) should also have carried one asterisk (.206*) to indicate that it, too, was significant at the .05 level.

- An error occurred in the article, "Temporal Changes in Work Content" (ASR, December, 1979), by Kenneth Spenner.

On page 971, column two, line 35 reads: "flects new jobs in occupational structures)." It should have read: "flects new jobs in the occupational structure)."

BEYOND METHODOLOGY: THE PLACE OF THEORY IN QUANTITATIVE HISTORICAL RESEARCH*

BARBARA LASLETT
University of Southern California

American Sociological Review 1980, Vol. 45 (April):214–228

This paper analyzes the relationship between theory and methods in that body of research that has come to be called "the new social history." First, an argument is made that the quantitative analysis of individual-level data that characterizes much of what is new in the recent sociohistorical literature is not only a methodology for conducting empirical research but also embodies an implicit theory of social organization that is both quantitative and individual. The power of such a theory to explain social change is limited, however, not only by technical problems associated with measurement and sampling error in historical research but also by the absence of an explicit causal component in the model. An alternative perspective, based on Marx's materialist theory of history, and which, it is argued, overcomes these limitations, is then presented. Empirical findings from research on the family in nineteenth century Los Angeles and Duncan's discussion of structural equation models, are used to illustrate how different theories of social change might be empirically tested.

There is a long tradition of debate about the relationship between theory and methods, between the explanation of empirical observations and the techniques used to generate those observations, in the history and philosophy of the social sciences. The increasing application of quantitative techniques to the analysis of historical data and the longstanding interest among social scientists in theories of social change provide an opportunity to reconsider some of the issues involved in this debate. This paper will present an analysis of the relationship between theory and methods in that body of research that has come to be called "the new social history." Examples will be drawn primarily, although not exclusively, from historical studies of the family.

The investigation of historical subjects is a particularly useful case for exploring the relationship between theory and methods in the social sciences. In contrast to research on contemporary issues, where the possibility exists that information not already available can always be collected (in theory, if not necessarily in practice), historical data cannot be infinitely expanded. Although new historical sources may be discovered, they cannot be manufactured. Under these conditions, explicit theoretical formulations would seem to be of particular value in helping to interpret the answers to historical questions that are often based on less than adequate source materials. Ironically, however, this has not been the case. As Murphey describes it (1973:148):

> Frustrated by the incompleteness of the historical record, and harassed by the knowledge that a malevolent fate will inevitably deny them some portion of the data needed to confirm even the simplest theory, many historians have even renounced theorizing altogether. . . .

The tendency to "renounce theorizing altogether" is one of the ways in which historians and sociologists have traditionally been distinguished from each other. The work of the former has usually been characterized as an effort to describe events, institutions, and individuals from some past era while the work of the latter is more often thought of in terms of an effort to formulate general laws of social organization that are transhistorical, although they are usually based on contemporary data. A more useful way of differentiating types of social science, and social scientists, might be the distinction between empiricists and theorists. I would suggest, however, that there is no necessary correlation between type of scholarly activity and disciplinary affiliation. Most historians *and* sociologists are empiricists; some historians and sociologists are theoreticians.

Paper presented at the 1979 meeting of the Social Science History Association. Thanks are given to William Bielby, Edna Bonacich, Robert Brenner, Alan Garfinkel, Nora Hamilton, Keith Hopkins, John Laslett, William Roy, James E. Smith, and Julia Wrigley for critical readings of earlier versions of this paper. Helpful comments were also made by Charles Tilly and another, anonymous, reviewer for the *ASR*.

This paper will attempt to show that the methodological approaches which have become a hallmark of the "new social history"—particularly the quantitative analysis of individual-level data—have mistakenly been assumed to provide the most appropriate basis for understanding social change *theoretically*. Thus, it will be argued that an implicit theory of social organization which is both quantitative and individual informs much of the most influential sociohistorical scholarship recently conducted and that this theory limits the ability to develop a causal theory of social change.

An alternative theoretical approach to understanding social change will then be explicated—one which, deriving from Marxist theory, focuses on the social relations and social forces of production, and views changes in class relations and material conditions as key factors in understanding both social organization and social change. An empirical example of changes in the family in 19th century Los Angeles will be used to demonstrate how existing statistical techniques can be employed to explore a theory of this kind. The Los Angeles examples will also be used to suggest that some important conceptual and methodological issues of a general nature are raised by using quantitative techniques to test a theoretical formulation that emphasizes qualitative changes in social organization over historical time.

Theoretical Issues in Historical Description

In recent historical family research, use of nominal listings (such as census schedules, tax rolls, city directories and parish records of vital events) as data sources has had two complementary consequences. First, such sources have made it possible to discuss the history of family life in more general terms than was previously the case because these listings often refer to whole populations rather than particular groups within them. Belief that the family in the preindustrial world was predominantly extended in structure may reflect the data on which this statement was based. Wealthier families tended to live in larger and more complex households (P. Laslett, 1972:154; Berkner, 1972; B. Laslett, 1975) and were also more likely to have left diaries, letters, and other types of literary and material artifacts, which might be preserved. Secondly, the use of various kinds of nominal listings has led to the development and application of techniques for constructing and analyzing historical data quantitatively (Wrigley, 1972; 1973); thus, statistical rather than intuitive criteria can be applied to estimating the reliability of observed family characteristics and the significance of relationships between, for instance, wealth and household structure (B. Laslett, 1975; 1977).

The use of quantifiable sources and advanced statistical procedures in their preparation and analysis and the application of sociological concepts has revolutionized the historical study of the family, but the revolution has not been a bloodless one.[1] While solving certain intellectual problems, others have been raised. As descriptions of the family in past times have become increasingly available, two primary questions about them can be asked: (1) How reliable and valid are these descriptions? and (2) How do they contribute to an understanding of the relationship between social change and the family?

Unfortunately, more attention has been given to the first of these questions than to the second. Thus, one major issue in historical family research is whether the family can best be investigated through research on the residential unit, the household (which census schedules, for instance, usually describe); on the nuclear kinship group (available through family reconstitution based on parish records); or on the extended kinship unit (which often requires the linkage of records beyond those indicating vital events only). (See, for instance, Berkner, 1975; Hareven, 1975a; Mitterauer and Sieder, 1979; Verdon, 1979.) This issue is, in essence, the problem of moving from the concept of "family" to its operationalization. In the fray of battle, however, the distinction between theoretical concept and measured variable has been lost.

---

[1] See Judt (1979) for a particularly vitriolic attack on recent sociohistorical scholarship. For a more useful analysis which, like Judt's, adopts a Marxist perspective, see Stedman Jones, 1976.

The "family" is a concept, an intellectual construct. In contemporary usage, it differentiates those individuals related to each other on grounds of kinship and residence from those who do not combine these characteristics to some degree.[2] Other definitions of "family" can also be considered, one of which might focus not on compositional characteristics of the unit but on social function. According to this perspective, the family could be defined in terms of its responsibility for reproduction—that is, for the renewal of life on a daily basis and intergenerationally.

The first observation, then, that can be made about the concept "family" is that its meaning is not self-evident. While no operationalization which focuses on kinship, residence, or function *alone* may be a complete account of the family as a social institution, empirical results based on any particular and necessarily partial operationalization are not unreliable simply because they are limited by it.[3] As Blalock (1964:5) has observed, there is "*an inherent gap between the language of theory and research* which can never be bridged in a completely satisfactory way" (italics in the original). Thus, debate on how to adequately operationalize the concept "family," while helping to refine empirical research techniques, cannot address the theoretical question of why studying the family is important for understanding social organization and social change.[4]

For instance, if the family's major social importance is seen in its socioemotional impact on individual lives, particularly through the socialization of young children, then operationalizing the family in terms of the coresident domestic group might be most appropriate. (P. Laslett's argument, 1972:65, suggests this perspective.) If, on the other hand, the family is thought of primarily as a unit of production, then operationalization in terms of the personnel involved in the productive activities that maintain the unit—whether kin or nonkin—would be necessary. (See Friedmann, 1978; Goldin, 1979; forthcoming; Goody, 1972; Hareven, 1978; Hareven and Vinovskis, 1978; Middleton, 1979; Tilly and Scott, 1978, for discussions of the family as an economic unit.) And if social reproduction is seen as the concept of primary theoretical interest, then the boundaries between the family and other social institutions become less clear; exploring reproduction in this more general sense may require the investigation of institutions such as schools, trade unions, and political organizations—in addition to the kinship or coresident domestic group. (B. Laslett, 1979, presents a discussion of this approach.)

Replacing debate over theories of the family, theories of social organization, and theories of social change, with arguments for and against the adequacy of residential vs. nonresidential kinship groups as ways to operationalize the concept "family" is, in my view, misleading because it implies that the basic problem in historical family research lies in unreliable (or inadequate) source materials. Limited as the historical records may be, the problem is, more often, inadequacies of the theoretical model. (See C. Tilly,

---

[2] This meaning of "family" is itself historically specific. Berkner (1972) points out that "the word family was not commonly used in German until the eighteenth century—before that people spoke of belonging to a house or household."

[3] It should be noted that each of the operationalizations mentioned in the text presents information that is limited in one way or another. The household unit excludes nonresidential kin while the ability to reconstruct familial groups beyond the coresident domestic group is limited by the often scanty records that make it impossible to trace a systematic sample of kinship units beyond the residential group.

[4] In general, more attention has been given to this theoretical question by Marxist social scientists than by others. For a review of some of the arguments from this perspective, see Humphries, 1977.

1979, for further discussion of this issue.) The problems involved in conducting empirical research have been confused with the difficulties of specifying the theoretical models that guide it. If this is the case, the solution lies not in more and better empirical data, necessary though that may be, but, rather, in the development of better (and necessarily more explicit) theoretical formulations.

Quantification and the Individual in Implicit Theory

Much of the sociohistorical literature which has emerged in recent years reflects a quantitative perspective—not merely as a methodology for conducting empirical research—but as a statement of what is important about changes over historical time. Questions have been asked, for instance, about the distribution of household types; the extent of social mobility; the number of births, marriages, and deaths; the density of kinship networks; the proportion of children enrolled in schools; and the amount of social inequality in past times. (See, for instance, Anderson, 1971; 1976; Berkner, 1972; Furstenberg et al., 1975; Hareven, 1975b; 1978; Hareven and Vinovskis, 1978; Katz, 1975; Knodel and Maynes, 1976; P. Laslett, 1972; Thernstrom, 1973; C. Tilly, 1978; van de Walle, 1976.) Sociohistorical research—with the primary objective of estimating changes in the *number* of extended and nuclear families (P. Laslett, 1972) or the *amount* of occupational mobility (Thernstrom, 1973) at different points in time—implicitly assumes that what is important about history is quantitative change.

From one point of view, an argument can reasonably be made that a concern with *amounts* or *numbers* is a necessary first step in the process of understanding social change; that accurate description of the changes that have occurred over time must be available before it is possible to develop explicit theoretical models which attempt to explain them. But this perspective on the relationship between theory and methods obscures both practical problems within the research process and important theoretical issues.

If social change is conceptualized in terms of variation in the distributions of characteristics—such as wealth, occupation, or family type—within a given population, and if this change is measured by estimating quantitative differences between these distributions at two or more points in time, then both measurement and sampling error (two of the methodological problems that quantification has been used to overcome) are of particular importance: it is on the basis of these distributions alone that an assessment is made about whether or not there is any change to be explained. Measurement and sampling error, of course, cannot be eliminated, both because the researcher does not control the data which forms the basis of her or his observations and, more importantly, because of the inherent gap between theoretical construct and empirical indicator of which Blalock (1964) speaks. Thus, measurement and sampling error pose particularly severe problems when quantitative differences are the criteria for assessing whether or not social change has occurred.[5]

But a further, conceptual, problem is raised by using changing distributions as a measure of social change, even if the relevant distributions can be measured with an acceptable degree of reliability. Duncan (1975:57) distinguishes two types of social change, one which reflects the changing features of a *distribution* of attributes and another which reflects changes in the *relationships* between attributes. When the former occurs, he says,

> . . . . One would then observe "social change" with respect to variances and covariances of the dependent variables. But in another sense no "social change" would be occurring, since the structural coefficients (which represent the relationship between variables) were staying constant. If, on the other hand, the latter should change, one would really be dealing with social change, in a deeper sense of the term.

According to this perspective, social change "in a deeper sense of the term" involves change in social relationships—in social organization as a whole—and not simply changes in the distribution of the individual components within the whole. While changes in distribution may identify variation in composition—that is, in the characteristics of individuals who fill positions within the social order—it does not necessarily mean that the social relationships and processes that define the social order itself have been transformed; social change "in a deeper sense of the term" does have such a meaning. This distinction—between social change that reflects changes in population characteristics (as measured by distributions of attributes) and social change that refers to changes in social relations (as measured by relationships between attributes)—has received relatively little attention, either methodologically or theoretically, within the "new social history."

---

[5] See Furstenberg et al. (1979), for an analysis of measurement error in one historical source. Measurement error is, however, also present in research on contemporary subjects although the ability to estimate its extent may, perhaps, be greater.

Thernstrom (1973), for instance, talks about the need to consider social structure in his study of Boston between 1880 and 1970. But the empirical indicator that he uses to discuss social structure is the distribution of individuals within the occupational structure. His analysis of changes in social structure focuses on the individual's experience of intra- and intergenerational occupational and social mobility—that is, on historical changes in the distribution of individuals within the occupational structure. A similar approach can be found in Katz's (1975) study of Hamilton, Ontario, between 1851 and 1861. Here, again, social structure is defined in terms of quantitative distributions of individual characteristics.

Four measures form the basis of Katz's operationalization of social structure. They are:

> (1) the occupational structure, or the proportion of the population engaged in various sorts of work; (2) the division of wealth, or the proportion of the wealth held by people in each economic rank; (3) the social and demographic identity of different economic ranks, or the characteristics of people with varying amounts of wealth; (4) the distance between the people of different social ranks. (Katz, 1975:44–5)

Information on each of these topics is obtained by counting the number of individuals in categories of some predetermined system of classification, such as occupations or dollars, and then performing an arithmetic computation on that information. Thus,

> . . . what is offered is not the theoretical construction of an object of study but merely the systematization of predefined data . . . a purely quantitative hierarchy of discrete groups who exist in no obvious relationship to one another. (Stedman Jones, 1976)

For Thernstrom and Katz, therefore, the investigation of social change is based on an implicit theory of social organization that is both quantitative and individual. As a consequence, social change "in a deeper sense of the term" can be neither identified nor explored.

It should be noted that there is nothing inherent in the use of *distributions per se* that limits their use to the description of individual characteristics; social relationships as well as individual attributes can also be described in terms of their distribution within a society. Furthermore, social relationships can also be viewed as being embedded in the distributions of individual characteristics. As Duncan points out (1975:166), in discussing *Inequality* (Jencks et al., 1972),

> . . . the "*b*" in his [Jencks's] model—say, dollars of income annually per number of years of schooling completed—is hardly a coefficient that describes merely the behavior of the *i*th individual. After all, it is *someone else* who pays him the income. . . . (Italics in the original)

But the impetus to identify and discuss social relationships from distributions depends on the theory of social change that informs one's research agenda; it is not determined by the technical approaches employed in the study of social change. Quite the contrary, one's theoretical approach—implicit or explicit—affects the methodologies that are developed and employed. Duncan's (1975) identification of structural coefficients as empirical indicators of social relationships is reflective of his theoretical view of what constitutes social structure, rather than being an inherent feature of the coefficients themselves.

Causal Theory in the Study of Sociohistorical Change

Most of the recent sociohistorical studies have been relatively inattentive to the problems of inferring causal relationships from statistical association. (Levine, 1977, is an exception in this respect.) But a causal theory, whether implicit or explicit, is always present in any act of historical interpretation. As Murphey (1973:102) says, "an interpretation always contains a causal model—whatever else it may tell us, it always claims to tell us why certain events or sequences of events occurred." A noncausal "theory" of history is, in essence, neither theory nor history. An attempt will be made in the following section of this paper to discuss the form and content that an explicit causal theory of social change might take.

One of the intellectual problems that has inhibited efforts to combine the traditional interests of historians and sociologists is the seeming contradiction between the former's efforts to preserve the *uniqueness* of place and time and the latter's efforts to develop *generalizations* about social organization and social change. This apparent problem can be expressed by the following question: If each nation or system of nations, each region, each category of individuals, can be properly analyzed only within a historically unique context because of the specific configuration of events and/or forces that define it, then how can a general theory of society be constructed?

What is needed is further specification of the meaning of "generalization" in sociohistorical studies.[6] The type of generalization most often encountered in sociological work is about the outcomes of change. For instance, William Goode (1963) concludes that the predominant change in the family that has accompanied industrialization, urbanization, and modernization is toward what he calls the conjugal family form. Goode emphasizes that the direction of change which results in this outcome may vary in different societies because the family systems from which the contemporary forms emerge are, for historical reasons, different. But his analysis focuses on a convergence in outcomes—toward the conjugal family system—and this result, he suggests (and supports with an impressive array of cross-national empirical data) is generalizable across societies and cultures, throughout the world.

An alternative perspective to the problem of "generalization" is neglected by this approach and is particularly appropriate for historical studies: it uses the term "generalization" to denote *causes* rather than *outcomes*.[7] In contrast to the search for generalizations about outcomes, which allows the possibility of multiple starting points, a search for generalizations about causes allows for multiple outcomes to result from a more limited set of causes. This one-to-many correspondence between cause and effect seems an appropriate theoretical approach to research where the importance of historical specificity and uniqueness is repeatedly demonstrated.[8]

Changes in the world economy, for example, affected land availability in colonial Andover, Massachusetts (Greven, 1970), in 18th through 20th century Estonia (Parming, 1979), on the American frontier in the 19th century (Easterlin, 1976), and in antebellum and post-Civil War Alabama (Barney, 1979). In each case, the availability of land declined but the consequences for the family and kinship structure varied. In Andover, movement of sons from immediate proximity and control of parents resulted; in Estonia, fertility reduction occurred; on the American frontier, a combination of these two outcomes took place; and, in Alabama, similar consequences were rapidly intercepted by the Civil War that has, ever since, eclipsed declining land availability as a prior cause of family and kinship change in the American South.

---

[6] Hempel's (1959) discussion of "the covering law model" is relevant to this issue. See Murphey (1973, chap. 3), for a review of the extensive critical debate which Hempel's position evoked.

[7] The part of the discussion which emphasizes the search for causes rather than outcomes was developed jointly with James E. Smith. See Smith and Laslett (1979).

[8] The error terms in, for example, structural equation models, allow multiple outcomes—but only as residual error, not as integral parts of a theory.

To search for causes that transcend spatiotemporal boundaries would remove the theoretical approach to the study of history from the traditional distinction between sociology and history. Traditional history has been dominated by descriptive research, with unique events—such as wars, depressions, and plagues—often assumed to be obvious causes that cannot be generalized across time or space. Sociologists, on the other hand, have traditionally followed the assumptions of the physical sciences requiring that there always be a one-to-one correspondence between cause and effect; by failing to allow for multiple outcomes from single causes, sociologists have, too often, disqualified themselves as accurate observers of the broad and varied sweep of history.

In order to develop a general, historically grounded theory of social change, a goal that is not necessarily shared by all social scientists—even among the most distinguished (see Roth, 1979:181, on Fernand Braudel)—studies that are concerned with this question need to search for (and test) explicit causal explanations for the varied outcomes that may be empirically observed. It is the ability to provide the causal inferences that link historically specific phenomena with general historical processes that would make truly explanatory the theory of which they are a part.

At least three types of causal explanations for historical change can be identified: (1) naturalistic, (2) individual, and (3) social. A naturalistic explanation of history would entail a belief that some outcome, such as the universality of the nuclear family, was inherent in—and an inevitable result of—characteristics of the human species. If this were the case, then the basic explanation for the organization of the family would be found in nature rather than in the social realm. Explanations of this sort can, of course, be found; life cycle variation in household and family structure in past times may provide one example.

Berkner (1972) found, in an analysis of household structure in an 18th century Austrian manor, that the proportion of extended and nuclear families varied by the age of the household head and suggested that household structure may systematically vary over the family life cycle. When the household head was relatively young, the coresident family was extended by the presence of the elderly parents of the head. The death of the parents changed the structure of the household, for a time, to nuclear. As the married couple aged, their children grew, married, and had children of their own. If one child and his or her own family of procreation remained within the parental household, the family would once again become extended in structure and would remain so until the death of the parents, whereupon the cycle would again proceed to the nuclear phase. These results suggest that there was a significant effect of age on the structure of the coresident domestic group in several pre- and early industrial settings. But social, in contrast to natural, change cannot be known from life cycle variation alone.

Duncan (1975:167) makes the point in statistical terms when he says that some distributions may change because of "alterations implicit in the very nature of the social structure and its initial conditions, as growth is implicit in the structure of an immature organism." Thus, variation in the age structure of a population over time is not necessarily the result of social change since it may be explained by natural processes of maturation. But if changes in the *relationship* between age and household structure are observed historically, then an explanation for them would be needed, and Duncan suggests why it is unlikely that such an explanation would be found in nature alone. He (Duncan, 1975:167) says, "The structures we hope to describe in our model are not fixed in the human gene pool nor dictated by the laws of physics. They can and do vary."

The second explanation—that social change is basically due to the actions of individual women and men in history—has had many proponents among social scientists. According to Roth (1979:195–206), Weber, for instance, considered this question in discussing the several possible levels of historical analysis. His moral concern over the importance of the individual as social and political actor in "swimming against the stream" of history, however, led him to think of history as "the causal analysis of individual phenomena."

Weber was not alone, either in his moral or political concerns or in his insistence that the individual was the most significant unit for both creating and understanding history. (See Stedman Jones, 1973, and Lukes, 1968, for further discussions of this question.) Gellner (1973:14), I think, provides an important response to this emphasis upon the individual in so much historical writing when he says,

> Perhaps, in the end there is agreement to this extent: (human) history *is* about chaps—and nothing else. But perhaps this should be written: History is *about* chaps. It does not follow that its explanations are always in terms of chaps. Socieites are what people do, but social scientists are not biographers *en grande série*.

Thus, although social change may result from what "chaps" do, it does not automatically follow that explanations of these actions, or their consequences, must consider individual factors only.

One theoretical basis for the third—the social—explanation of history already exists within the social science literature, although it has received relatively meager empirical attention in quantitatively oriented research: Marx's materialist theory of history. In brief, this theory (Marx, 1972:4) states that:

> In the social production of their life, men enter into definite relations that are indispensable and independent of their will, relations of production which correspond to a definite stage of development of their material, productive forces.

The theory further suggests that social change can be understood in terms of the contradictions between the social relations and social forces of production that develop over historical time.

Thus, an explicit theory of the organization and change of societies, which rests on social relations, not on natural or individual causes, has been proposed. The following section of this paper will apply this formulation to a general understanding of changes in the family over historical time and then to a specific example from 19th century Los Angeles. In the process of considering this empirical example, Duncan's (1975) proposed solution to some of the statistical problems involved in the empirical study of social change will be applied.

A Materialist Theory of the Family in History

There are two basic requirements for the survival of any society that can be said to have a history: production and reproduction. Both are required for the maintenance of life from day to day, and for survival across generations. While both production and reproduction are necessary for human survival, they do not necessarily have equal force as causes of social organization or social change. The formulation presented here assumes that the immediacy of daily needs has causal priority over longer-term intergenerational needs. If this is the case, then, the social organization of production, by defining the conditions which affect access to the material goods necessary for life on a day-to-day basis, should have causal priority over the social organization of reproduction.

But reproduction is also necessary if survival is to occur beyond a single life span; the social organization of reproduction should, therefore, have a direct effect on the development of any social system over time. Thus, the family, as the major social institution responsible, historically, for reproduction, while operating within limits set by the social organization of production, should not be wholly determined by it; the family should have an independent effect on history. The degree to which this statement can be empirically validated would provide a test of the causal priorities contained within the model.

As the term is used here, "reproduction" refers to the activities, institutions and relationships necessary for the maintenance and renewal of life. While the specific content of reproductive activities and relationships may vary historically, they invariably include the sexual and psychological dimensions associated with procreation, and the nurturing activities associated with care, protection, and socialization of children. Given its historical responsibility for these activities, the family may be seen as an institution with its own unique goals; it need not, however, be completely defined by these goals. Thus, variation in the family's range of activities may, in some historical periods, extend beyond the sphere of procreation and socialization to include production itself and, at other times, may exclude certain aspects of socialization and nurturance, such as formal education or the care of the elderly. When the former occurs, the study of production and reproduction are, institutionally, the same; they both occur within the family. When the latter is the case, the study of reproduction may require investigation of institutions outside the family.[9]

This brief theoretical statement is, obviously, highly general and abstract. Presenting its content in more concrete terms is beyond the scope of, or reason for its inclusion in, this paper. (See B. Laslett, 1979, for a more detailed statement.) Certain features of the formulation, however, can be identified even in the abbreviated form presented. In the first place, causal priority is explicit in the theory: the social organization of production, by structuring access to the material goods necessary for daily life, explains *why* other aspects of social life and social organization, including the family, have some of their particular characteristics. But the theory does not imply that the social organization of production *determines* family structure or behavior. As an institution with its own responsibility—that of reproduction—the family will attempt to fulfill its own goals and, by so doing, will have an independent effect on history, given the necessity of reproduction for intergenerational survival of the society as a whole.

In addition to making explicit which social factors have causal priority *and* the limitations of those factors as causes, a second implication of the formulation can be identified, even in the brief and general form in which it has been presented. If the social organization of production has primary explanatory power in relation to the family, then—when the social organization of production changes—the family should also change. The social organization of production, however, is a concept that refers to a pattern of relationships in the society as a whole, not only to individual units within it. Thus, a third implication of the formulation can be identified—one which suggests that different levels of theoretical analysis may be necessary for understanding the family, or reproduction in general, under varying historical conditions.

Historically, the development of capitalism has meant that the division of labor in the process of production has become organized on a world scale (Wallerstein, 1974). Units of reproduction, however, are considerably smaller. Whether thought of in terms of the co-resident domestic group, of the extended kinship system, or even of the nation state (which provides some material resources for reproduction in the modern world), the units of analysis most appropriate for investigating *repro*duction are considerably more limited in scope than is the case for *pro*duction.

The general practice in most recent historical family research, however, is to relate some socioeconomic characteristic of the individual with some feature of her or his family organization or behavior. If the organization of production is most adequately understood as a feature of the society as a whole, however, such an analytic procedure cannot adequately test the proposed relationships between production and reproduction, or even between the economy and the family. Thus, under some historical conditions, such as those that describe the organization of production under capitalism, investigating such a relationship may require that attention be paid to different *conceptual* levels of analysis: the social organization of production as *a whole* as well as the behavior and attributes of individual units within it.

Marx's theory is specific about those

---

[9] For additional discussions of the relationship between production and reproduction which provide a somewhat different focus, see Meillassoux, 1972; 1973.

aspects of the social organization of production that are theoretically important. He distinguished different modes of production (Marx, 1964; 1967) and identified class relations and the productive forces as key causal factors in explaining empirically observed phenomena, in both the past and the present.[10] To test such a theory in relation to changes in the family under capitalism, it is necessary to attend to both the specific features identified by Marx as key to understanding the social organization of production and the units of reproduction which historically have been more localized and individual. This issue will be discussed further in the context of an empirical example of changes in household structure in Los Angeles, California, between 1850 and 1870 (B. Laslett, 1977).

Household Structure and Social Change in 19th Century Los Angeles

Within the twenty years between 1850 and 1870, Los Angeles developed from an isolated, self-sustaining, and largely barter economy into a dependent, money economy (Fogelson, 1967). Although the economy was largely agricultural in both years, the nature of economic activity had changed: farming had become commercialized and was increasingly organized for purposes of exchange, rather than for purposes of subsistence. From a Marxist point of view, these changes would have resulted in changing class relations and changes in the forces of production which, together, describe the organization of production in the society as a whole. It is from this perspective that the empirical findings of changes in the family will be considered.[11]

In 1850, 29% of the households in the city of Los Angeles were nuclear in structure; by 1870, this proportion had increased to 46%. This change, however, appears to be due to changes in the distribution of laborers in the two time periods. The proportion of laborers had increased from 18% to 30%, and being a laborer was significantly related to heading this kind of domestic unit in both years. But, from another point of view, no social change in relation to the laborers' families had occurred since the structural coefficients, which describe the relationships, at the two points in time, between being a laborer and heading a nuclear family household, were invariant. This reasoning, however, does not explain the decline in the proportion of extended family households between 1850 and 1870 (from 16% to 7%).

Although the distribution of farmers remained nearly constant in the two time periods (19% in 1850, and 21% in 1870), the structural coefficients, which describe the relationships between being a farmer and heading an extended family household, declined in magnitude. If this change in structural coefficients is to be explained in *social* terms, Duncan's (1975) discussion would suggest that it is in changes in social relationships that the answer will be found.

But a question may also be raised about why the proportion of laborers had increased between 1850 and 1870. An answer would tell us nothing about changes in the structure of laborers' families during this time period, since the association between being a laborer and heading a nuclear family household was invariant over the twenty-year period. It might, however, tell us something about changes that were occurring in the social organization of production; and any theory which can explain *both* changing distributions and changing relationships is clearly more powerful than one which can explain one type of variation but not the other.

Two questions of interpretation are raised, then, by the empirical findings discussed: (1) Why did the structural coefficients estimating the relationships between being a farmer and heading an extended family household change over time? and (2) Why did the proportion of laborers increase? Both of these questions involve conceptual, and not merely empirical, issues. They require, at the very outset, the statement of a *theory of history* which, as already argued, must inevitably include a *causal* component. Both the theory and its causal element need clear explication.

---

[10] It is this specification that differentiates Marxist theory from other formulations which may also focus on relationships between parts of the social system (Smelser, 1959).

[11] Detailed documentation of the brief description of changes in Los Angeles cannot be presented here. It will be available in the author's research on the family in Los Angeles between 1850 and 1900. For early results from this study, see B. Laslett, 1975; 1977; 1978.

Consistent with the materialist approach to the history of the family that has already been presented, a response to the first question—why the relationship between being a farmer and heading an extended family household changed over time—would be sought within transformations in the social organization of production as a whole. Since the occupational structure may tell us something about this aspect of social organization, an answer to the second question—why the proportion of laborers increased—may provide an additional test of the theoretical approach used to answer the first question.

From a Marxist perspective, one consequence of the economic changes that occurred in Los Angeles between 1850 and 1870—the increasing commercialization of agriculture, the gradual transformation of the economy from production for subsistence to production for exchange—was that the class structure of the society as a whole was being transformed. Producers were increasingly becoming wage workers, and the means of production were increasingly being used for purposes of accumulation rather than for purposes of consumption. But how do these changes allow us to understand the relationship between social organization and household structure? Four separate opportunities to answer this question are available in the empirical example being discussed.

Laborers, in both 1850 and 1870, were more likely to be dependent on an exchange of labor power for the material goods necessary to maintain a family, and in both years they were more likely to head nuclear family households. Changes in the social organization of production did not affect these relationships because, in both cases, laborers' access to the means of production was the same.

Farmers, in contrast, were less likely than laborers to be wage workers in either year. But the relationships between their *individual class position* and the type of household they headed did change. Why? For farmers, the development of capitalism—which involved specialized production for exchange rather than diversified production for consumption—meant that in 1870 they were more like laborers than they had been in 1850; they, too, had to engage in market exchange—of agricultural products, although not of their own labor power—in order to obtain the material resources necessary for reproduction. The social meaning of individual class characteristics had changed because the social organization of production as a whole had been transformed.

Beyond suggesting why the commercialization of agriculture explains the observed change in the relationship between being a farmer and household structure, the theory can also explain why the proportion of laborers increased between 1850 and 1870. Although agricultural activity dominated the local economy in both years, the proportion of the population who were land owners declined, from 53% to 38%, between the two decades (B. Laslett, 1977). The separation of producers from the means of their own subsistence is a central feature of capitalism as a mode of production and, according to Marx, a basic cause of the dynamics of change within the system as a whole. Thus, the increasing proportion of laborers would also appear to be explained by the development of capitalism in Los Angeles.

Whether or not Marxist theory can, in the final analysis, adequately explain this or other changes in household structure—or other features of family life, in places and time periods different from Los Angeles in the 19th century—must await the results of further empirical research. Such research, however, must be explicitly informed by a causal theory in which particular aspects of social organization are identified as significant for understanding historical change.[12] Research designs and measurement procedures which address these specific features of social relationships are necessary for testing the theory's validity. To test such a theory, techniques must be developed which can adequately estimate changes in the social relations and social forces of productive activities over time, and not merely changes in the distribution of socioeconomic characteristics of individuals within a given society. Thus, Marxist theory, like any other, raises methodological as well as theoretical and empirical problems.[13] But, unless relevant aspects of this (or an alternative) theory are made explicit, no amount of attention to isolated measurement or statistical problems will provide the basis for advancing our understanding of social change.

---

[12] The general theory presented briefly in this paper also provides a basis for explaining how the needs of the family—or reproduction—contribute to social change. (For an elaboration of these ideas, see B. Laslett, 1979.) They will be explored empirically in the larger study of Los Angeles in the second half of the 19th century, of which the empirical example discussed in the text is one part.

The adequacy of research designs for historically grounded studies of social change are also affected by the theoretical model which they are attempting to test. It is only when an empirical investigation is comparative over time that the structural coefficients would be available that could indicate whether or not social change had occurred. It is therefore striking how much historical family research does *not* have temporal variation beyond the individual life cycle built into it (see, for instance, B. Laslett, 1975; Hareven, 1978).

It is not sufficient, however, for historical research to encompass *any* temporal period. A study that wishes to measure the effects of social change must be certain that the theoretically relevant changes actually occurred in the span of years covered by a particular study. Research on Los Angeles that stopped in 1870, for instance, would not be able to measure many of the effects of capitalism on the family since its major developments did not occur until after the mid-1880s. Thus, some historical knowledge is necessary for designing research which can adequately assess the effects of those changes that are identified as theoretically important. While this requirement should not be troublesome to professional historians, it cannot necessarily be taken for granted among sociologists. Just as social historians have had to become familiar with statistical methodology that is routinely taught to sociologists, so sociologists who wish to engage in historical research must develop their sensitivity to, and empirical knowledge of, different historical eras and events.

Conclusion

A discussion has been presented that suggests the need for explicit attention to the basic assumptions which underlie different theories of history since they affect the empirical research that is done. Little advance in the study of social change will be achieved if research is informed primarily by implicit theory or by the technical problems relevant to analyzing quantitative historical data. This is not because technical matters are unimportant, but because different theories of history pose different empirical and methodological problems. Technical decisions are dependent on, not independent of, theory. It is important that discourse in quantitative social history goes beyond methodology.

Unless the relationships between theory and methods are explored—which requires that theories become explicit and their causal components be specified—our empirical knowledge about past times may improve at a rapid pace without necessarily providing better explanations for social change. This paper has discussed several issues relating to theories of social change and the family, and the methodological problems posed by the wish to empirically test those theories' validity with quantitative historical data. The argument which it presents, however, has implications beyond the historical study of the family—implications for the types of generalizations appropriate to research on contemporary, as well as on historical, subjects.

---

[13] One particularly important statistical problem which Marxist theory poses is how to measure the effect of temporal change when the need to minimize measurement error requires that the relevant variable be operationalized in qualitatively different ways in different time periods. If the social institutions of reproduction or production have changed over time from, for instance, a broader to a narrower kinship unit in the case of the former, or from the family to the firm in the case of the latter, then how can the quantitative effects of changes in the same functional units be estimated if different operationalizations must be used to measure them reliably, over time? To require that all terms that refer to the same phenomenon, or function, be measured in the same way in a time series analysis, regardless of the social realities of the historical period to which they refer, presents a statistical barrier to the quantitative study of social changes that refers to qualitative transformations in social relationships. Given the ingenuity of statistically oriented social scientists, however, I have no doubt that a solution to the problem, once identified, can be found.

If, as in 19th century Los Angeles, the relationship between being a farmer and heading an extended family household is not invariant over time but is affected by the social organization of production within which farming occurs, and if social organization as a whole has undergone qualitative transformations, over time, then no generalization about the outcomes of the relationship between farming and household structure can be universally valid. If relationships between variables which describe individual characteristics are affected by changes in the social organization of production as a whole, then generalizations which ignore its key features—the social relations and social forces of production—will be unable to accurately interpret the findings that historical research makes available. And if qualitatively different forms of social organization have existed over time, then sociology can no longer justify its ahistorical propensity by referring to the goal of generating empirically validated general theory. Sociological theory, to be empirically valid, must be historically specific. This is, perhaps, the most important implication for contemporary sociology to be drawn from historical research.

Most of the substantive questions raised by recent sociohistorical scholarship still require empirical answers. For advances in this direction to be made, however—in studies of the past, of the present, or of the processes by which the one was transformed into the other—the theoretical models which inform such research need to be made explicit. Only when this occurs can the rigorous methodological requirements necessary for testing and developing scientific theories of historical change be achieved. Research on past times, like research on contemporary questions, can provide empirical answers only to those questions that are asked, and theoretical work is necessary for asking better questions.

FIREARMS OWNERSHIP FOR SPORT AND PROTECTION: TWO DIVERGENT MODELS*

ALAN J. LIZOTTE
Emory University

DAVID J. BORDUA
University of Illinois, Urbana-Champaign

American Sociological Review 1980, Vol. 45 (April):229–244

A rationale for investigating subcultures of firearms ownership is developed. Two gun-owning populations are investigated by using survey data for the State of Illinois, those who own guns for sport and those who own guns for protection. Models of individual level gun ownership for sport and for protection are constructed and tested. Sporting gun ownership appears to be subcultural. Sporting gun ownership can be predicted by using family socialization variables and indicators of contact among members of the subculture, independent of situational variables. Protective ownership has none of the trappings of a subculture. It does not respond to family socialization and indicators of contact with other people who own guns for protection. Further, there is no indication of a subculture of violence among protective gun owners. Violent attitudes and behavior do not predict protective gun ownership. In fact, a situational variable (county violent crime) was the only predictor of gun ownership for protection. Further, gun ownership for protection and gun ownership for sport were found to be independent events, with no joint probability of occurrence. This suggests that the impetus for a subculture of protective ownership could not be a logical extension of a subculture of firearms ownership for sport.

Introduction

Previous research on firearms ownership displays several shortcomings. Studying firearms ownership as a social problem from the subculture of violence perspective and certain methodological errors in previous research have limited our knowledge of the area. First, firearms ownership is often studied as a social problem, rather than as a behavior pattern. In this vein Newton and Zimring (1968) study *Firearms and Violence in American Life*; Wright and Marston (1975) investigate "The Ownership of the Means of Destruction: Weapons in the United States"; and Kukla (1973) considers *Gun Control*. This literature devotes little or no attention to the sporting use of firearms or to gun ownership for protection in response to crime.

Second, many who study firearms ownership focus on the "subculture of violence" thesis of Wolfgang and Ferracuti (1967). For example, Hackney (1969), Gastil (1971) and Reed (1972) argue that the high incidence of homicide in the South and high rates of southern gun ownership are due to a subculture of violence in that region. They ignore gun ownership for sport and for defense. Others have argued that there could be several uses of firearms. We (Bordua and Lizotte, 1979) suggest that a sporting culture is not only dominant in the gun world, but it is also unrelated to a subculture of violence. We argue that one should study the interrelationships between the legitimate gun culture, a subculture of violence, and ownership for protection.

Third, when gun ownership for protection is studied, analyses are fraught with conceptual and methodological errors. Only a few studies (Bordua and Lizotte, 1979; O'Connor and Lizotte, 1978; Kleck, 1979) have used multivariate methods to ferret out complex relations between different aspects of firearms ownership for protection. Firearms ownership for protection could be a complex phenomenon. Attitudes towards violence, toward blacks, experiences with violence, crime and perceptions of crime, the effectiveness of the criminal justice system and the fear of crime might relate to gun ownership for protection. Poor data, weak

We would also like to thank an anonymous reviewer for helpful stylistic and theoretical comments. This research was partially supported by a grant from the Illinois Law Enforcement Commission.

conceptualization of the theory and inadequate methodologies have all compounded the problem.

This research will attempt to address these methodological and conceptual problems in studying patterns of firearms ownership. Particular attention will be devoted to the fear of crime and in turn to protective behavior as a response to that fear. But the sporting use of firearms and its interplay with crime and protection will also be considered.

Sociological Theories of Firearms Ownership

Sociological explanations of firearms ownership are of two basic types. Either they lean heavily toward a subculture of violence explanation, which can be subsumed under a rather specific literature on cultural theories of deviance, or they oppose the subcultural models by introducing "situational" or structural considerations to show that the cultural effects are spurious. Few studies combine cultural and situational factors to predict firearms ownership. Still fewer extricate their models from the rather ideological "deviance" perspective on gun ownership.

Recent proponents of the subculture of violence thesis place heavy emphasis on the function of firearms in the violent subculture. Gastil (1971) gives culture a secondary position to gun ownership in causing interpersonal violence. But Wolfgang (1958) states that high homicide rates are intrinsically related to culture and not necessarily to weaponry.[1]

Hackney (1969) and Reed (1972) also posit that high rates of interpersonal violence in the South are indicative of a southern subculture. However, their theory is closer to Wolfgang's original formulation. They suggest that "this differential in gun ownership is the result of a violent turn of mind rather than the cause of the violence" (Hackney, 1969:518). Thus, Hackney suggests that guns do not cause crime, but that violent individuals buy guns and use them to perpetuate crime.

The approach assumes that cultural factors drive people to own guns and use them violently. Indeed, implicit in the theory is the assumption that all gun owners are potentially violent and that gun ownership is an indicator of this potential. Loftin and Hill (1974), O'Connor and Lizotte (1978), and Bordua and Lizotte (1979) focus on several major inadequacies of the Gastil-Hackney-Reed thesis, while Erlanger (1975) casts doubt on Wolfgang's original formulation of the thesis.

Etzioni and Remp (1973:141) suggest that any realistic study of firearms ownership "requires a detailed examination of the varying ways in which firearms are presently being used in the U.S." More specifically, Cohen (1955:72) states that "a complete theory of subcultural differentiation would state more precisely the conditions under which subcultures emerge or fail to emerge, and would state operations for predicting the content of subcultural solutions." In the same vein Loftin and Hill (1974:724) "show that a more definite assessment of the role of culture and situational variables on interpersonal violence will require specifying a theoretical model which would allow for a full range of cultural and structural variables." In the following section we develop models of firearms ownership for sport and protection. In doing this, we attempt to consider a wide range of cultural and structural variables.

There are three basic reasons—sporting, protection, and criminal—for owning guns. Since this research studies patterns of legal firearms ownership, it will study sporting and protection patterns of ownership.

There are three possible subcultures which this study will consider. The first two are subcultures of sport and protection. The third is a subculture of violence which is centered around protective gun ownership. If gun owning subcultures do exist they arise from situational and structural conditions. These conditions vary with reasons for ownership. That is, owning firearms for sport will result from a different set of situations than owning firearms for protection. Furthermore, cultural support mechanisms operate to legitimize and justify different types of ownership for the individual. Thus, people call upon cultural legitimations as normal responses to situations they face.

---

[1] In their later work Wolfgang and Ferracuti (1967) change the tack to place more emphasis on firearms in the subculture of violence. We prefer to rely more heavily on the earlier empirical work of Wolfgang for substantive support to this argument.

We will accept the existence of a subculture when three conditions are met. First, some subgroup of people must manifest a behavior, norm, or attitude which is different from those of the larger society (Wolfgang and Ferracuti, 1967:105). For example, a member of a sporting gun subculture must, at least, own a gun for sport. Similarly, members of a protective subculture must own guns for protection. Members of a subculture of violence centered on protective ownership must own a gun for protection and exhibit violent attitudes and/or behaviors which would typify this group.

Second, in order for a subculture to exist, there must be some mechanism which will produce an intergenerational transmittance of the behavior, norm or attitude. For example, Gastil (1971), Hackney (1969), and Reed (1972) all place heavy emphasis on the family as the mechanism of socialization into a subculture of violence. The socialization requirement means that a subculture must be tenacious enough to transcend the situational concerns of one generation, and for the behavior to be passed on to the next. Without this capacity, the behavior, norm, or attitude would be ephemeral and not indicative of a subculture (see O'Connor and Lizotte, 1978).

Third, for a subculture to exist there should be some indication of contact among members of the group. For example, Cohen (1955:104) argues that members of a subculture should "gravitate toward one another . . . to establish new norms." As Cohen suggests, this contact among members is necessary not only to keep the behavior, norm, or attitude alive, but also to develop new norms and subcultural responses.

For a subculture to exist, each of these three conditions must hold in the context of situational controls. For example, Wolfgang and Ferracuti (1967:105) state that

> a given conduct, norm, or set of values must function to govern the conduct in a variety of situations in order to classify that norm or value set as a subculturally expected or required response and not merely as a statistical modal reaction.

Hence, in order to test for the existence of subcultures, one must equalize the effects of situation across hypothesized subcultural groups to evaluate differences in conduct or other cultural indicators. That is, a subculture will exist in the formal sense when our three conditions are met, and when they are independent of situation.

Sport Ownership Theory and Model

At the county level we (Bordua and Lizotte, 1979) find inferred socialization factors and situational concerns to be most important in predicting sporting culture. A similar argument is made here at the individual level. Recall that there are three conditions which must be met to support a finding of a subculture of sporting gun ownership. They are: sporting ownership, socialization, and contact among members of the subculture. Bakal (1966), Newton and Zimring (1968), and Bordua and Lizotte (1979) all argue that military service socializes men into gun ownership. They assume that men become familiar with firearms in the military. These men then continue with the orderly use of firearms when they return to civilian life. But not all military personnel carry firearms. Indeed, many are given no small-arms training at all. Hence, a veteran who carried a firearm in the military should be more likely to own a gun as a civilian than a veteran who did not carry a gun. Similarly, those in a combat zone would be better trained in small-arms use than those who were not. Finally, soldiers in combat should be more familiar with firearms than others. Hence, a scale will be developed which reflects involvement with firearms in the military. This scale should predict the legal, culturally ordered use of firearms for sport.

The civilian counterpart of this socialization into gun use is the individual's early training into the proper use of firearms. Therefore, individuals who acquired their first gun early in life should be more likely to have been trained to use a gun. Further, this training should translate into firearms ownership for sport in later life. Similarly, if one's parents owned a gun, socialization should operate which would affect that person's ownership in later life.

Other socialization factors could operate. Situations and an opportunity structure should combine to create a favorable social climate in which the sporting use of firearms can thrive. Here socialization into ownership and ownership itself are quite aboveboard, socially sanctioned and even encouraged. In this vein the sporting use of firearms should be something of a family affair. Hence, if the respondent's parents owned a gun, the respondent should be more likely to own one. Similarly, if the respondent owned a gun at an early age, that person should have a higher probability of continued use in later life.

There are three indicators of contact among members of a subculture of sporting gun use. First, given the social acceptability and even desirability of firearms ownership in this group, other members of the respondent's household might own guns for sport, hunt together, and belong to shooting clubs. Second, communication among members of the subculture could be carried out through more abstract forms. As we point out (Bordua and Lizotte, 1979), those individuals who subscribe to sporting oriented magazines are expected to be more likely to own guns for sport. Magazine subscription would not only indicate communication of subcultural ideas and values, but it would also indicate involvement in the intricacies of the culture beyond shooting and hunting. Third, high hunting rates in counties imply that a subculture of sport could be active, and that there is significant contact among members of the subculture in the county. That is, counties with high hunting rates could supply the cultural backdrop for individuals in the county to be involved in a subculture of sport.

Independently of the subculture, a certain opportunity structure could exist which would support sporting firearms ownership. Since hunting is primarily a rural phenomenon, rural people should be more likely to own guns for sport. Also, those who grew up in a rural environment are expected to carry their background with them, and to be more likely to own guns regardless of the size of place in which they currently live.

Additionally, men should be more likely than women to own guns for sport. A negative relation between education and gun ownership for sport should exist. However, there should be a positive relation between income and sporting ownership. Highly educated individuals are probably more liberal and, therefore, support gun control, while those with high incomes find it easy (monetarily) to buy a gun.

Protection Ownership Theory and Model

Independently of other concerns, individuals could own guns for protection either because they belong to a subculture of protection, or because they are members of a subculture of violence in which protective firearms ownership plays a central role. If a subculture of protection exists, we would expect those who own guns for protection to have contact with other members of the subculture. That is, they should have friends who also own guns for protection. We would also expect a subculture of protection to have a mechanism for transmitting protective gun owning from generation to generation. One possible mode of socialization would be the family; another might operate indirectly through a subculture of sport. For example, if no socialization into protective gun ownership is found, and a subculture of sporting gun ownership exists, it could indicate considerable overlap between sporting and protective ownership among individuals. This overlap would imply that there is an indirect effect of socialization on protective gun ownership through sporting gun ownership. Of course, these relations should be independent of the current situation.

A subculture of violence which centers on protective ownership should meet the conditions stated for a subculture of protection. In addition members of the subculture of violence should exhibit violent attitudes and behavior.

Of course many other factors, independent of either subcultural response, could predict gun ownership for protection. The structure of the model to be tested is as follows: Fear of crime (see McIntre, 1967 and Furstenberg, 1971) could be the primary motive for home defense, and, hence, for firearms ownership for protection (Feagin, 1970). There are six basic factors which could motivate fear of crime in an individual. They are: crime, experiences with violence and victimization, racial attitudes and violent attitudes, the perceived crime rate, the perceived effectiveness of the police and courts, and the proximity of blacks. Also, social characteristics of individuals such as income, race, and sex could operate along with situational and attitudinal variables.

The basic relations are as follows: The crime rate in a county could affect the individual's perceptions of that county's crime rate, perceptions of the effectiveness of the police and courts, and the individual's personal experiences with violence or victimization. Additionally, the crime rate might be a good predictor of the respondent's knowledge of others who own a gun for protection, home defense measures taken by the respondent, and gun ownership for protection on the part of the respondent. People need not fear crime in order to own a gun for protection. A milieu of crime might make the individual less fearful but more willing to take defensive measures. Alternatively, some people might *not* be fearful *because* they own guns for protection.

Specifically, when the crime rate in a county is high, the respondent could know other people who own guns for protection. Respondents in high crime counties might perceive the courts and police as ineffective. Where crime is high, individuals should perceive a high crime rate. Finally, high crime should predict the respondent's experiences with violence and victimization. With these effects and the effects of social characteristics controlled, only a trivial relation between actual crime and the fear of crime should be found.

The crime rate is not as important as the perceived effectiveness of the criminal justice system in determining fear of crime (Reiss and Bordua, 1967:28). The same argument, independent of other situational and attitudinal factors, is made for relations between the crime rate, home defense, and, ultimately, owning a gun for protection. The policy implications are intriguing. Even in the context of a high crime rate, large-scale reductions in gun ownership for protection could be brought about by convincing individuals that the criminal justice system can and will protect them.

Individuals could see a trade-off between the ability of the police and courts to protect them and defensive behavior to protect themselves (Feagin, 1970). Even when the objective reality of crime is put aside, those people who see the police and courts as being ineffective in protecting them from crime might take measures to protect themselves (Reiss and Bordua, 1967).

Owning a gun for protection could be a consequence of several other factors. It could be the logical extension of a general home defense orientation. One mode of behavior for individuals who are vulnerable to crime is to increase their personal security, which leads them to a general home defense orientation and the acquisition of a gun. Buying special locks for one's home, obtaining a guard dog, installing burglar alarms, and the like, are of the very same variety of protective response as buying a gun. Similarly, being female, living alone, having a low income, and living in a large city are all factors which relate to the individual's defense posture with respect to crime.

We (Bordua and Lizotte, 1979) find some evidence at the county level to suggest that individuals use the proximity of a young black population as an indicator of crime. If this is true, the proximity of blacks to one's neighborhood could lead to certain racial attitudes that would encourage a home defense orientation in general and owning a gun for protection from blacks in specific. The relations between the proximity of blacks, the fear of crime, and defensive behavior could hold for both blacks and whites. Regardless of their race, people associate black neighborhoods with crime. This would lead to fear and defensive behavior (Furstenberg, 1971).

Data and Methods

The data for this study consist of an initial sample of 764 telephone interviews of heads of household in the state of Illinois. The data were collected in the spring of 1977 by the Survey Research Laboratory (SRL) at the University of Illinois. In downstate Illinois the sample of heads of household was randomly selected from telephone directories. Random digit dialing was used in Chicago.

The overriding methodological problem in the analysis is related to the dichotomous dependent variables, firearms ownership for sport and firearms ownership for protection (Lizotte, 1979). When analyzing the variance in a dichotomous variable using ordinary least squares (OLS), several assumptions are violated (Theil, 1971; Kmenta, 1971; Nerlove and Press, 1973; Palmer and Carlson, 1976). Many alternative methods for analyzing dummy dependent variables have been suggested. These include weighted least squares, Probit, Logit, Logistic models for categorical data, and Modified Logistic Response Models.

While being directly analogous to the Goodman system, the Nerlove-Press (1973) modified logistic response model has certain advantages. It allows one to consider the effect of continuous, as well as polytomous, exogenous variables. It also permits easy computation of MLE conditional probability estimates for several qualitative polytomous endogenous variables along with the direct effects of either continuous or polytomous exogenous variables.

Of the techniques discussed, the Nerlove-Press technique is clearly best suited to this study; OLS, WLS, and WLS with grouping simply do not adequately deal with the problems of heteroscedasticity *and* the nonnormal error term encountered in dummy variable analysis. Traditional Logit and Probit require large samples to asymptotically approach MLE. Since this analysis is limited to 764 cases, it would not seem wise to use these techniques. Additionally, the continuous nature of the Probit estimates makes interpretation difficult. WLS with grouping and Logit are also undesirable because they require grouping data on x variables, which has the effect of constricting the number of variables or categories of variables in small sample sizes. The Goodman log-linear system (Goodman, 1972a; 1972b) requires all variables to be polytomous, which destroys the true nature of continuous data. The Nerlove-Press model suffers from none of these faults. Further, the equation estimated by the Nerlove-Press system,

$$p(Y) = \frac{1}{1 + e^{-(a + bx_1 + \dots + bx_G)}}, \qquad (1)$$

provides a direct OLS analogy.

The variables were coded in the following way. Exogenous variables common to both models are shown in Table 1. Variable names are listed in the left-hand portion of the table, while descriptions of those variables are shown at the right. For example, the table shows that sex is coded 0, for female respondents, and 1, for male respondents. Sex, race, age, income, education and size are variables which appear in both the sporting and protection models. Their coding is straightforward with one exception. The Nerlove-Press program finds it difficult to converge on an estimate of the asymptotic variance-covariance matrix when exogenous variables are allowed to take on values above 9.99. To facilitate computational ease, variables with values above 9.99 have been scaled accordingly. For example, age could take on values up to 99 years. Dividing age by ten yields a maximum value of 9.9. This preserves the continuous nature of the variable while allowing for computational ease. Education has been divided by ten, and size has been divided by one million.

Variables particular to the model of sporting gun ownership are shown in the second part of Table 1. Only the coding of those variables which need more elaboration than given in the table will be discussed. Region 16 is an indicator of childhood residence in the southern part of the United States. Age at first gun is the re-

Table 1. Description of Variables Common to Both the Sporting and Defensive Models of Gun Ownership, and Variables in the Sporting Model

Variable Name	Description of Variables
Both Models	
Sex	0=Female, 1=Male $\bar{x}$ = .43, S.D. = .50
Race	0=Nonwhite, 1=White $\bar{x}$ = .88, S.D. = .32
Age	years/10 $\bar{x}$ = 4.48, S.D. = 1.70
Income	1<\$5,000; 2=\$5,001–\$10,000; 3=\$10,001–\$15,000; 4=\$15,001–\$20,000; 5=\$20,001–\$25,000; 6=\$25,001–\$30,000; 7>\$30,000 $\bar{x}$ = 3.69, S.D. = 1.77
Education	years through 16; 17=some graduate school, 18=graduate degree; years/10 $\bar{x}$ = 1.29, S.D. = .27
Size	size of place; population/1,000,000 $\bar{x}$ = .80, S.D. = 1.36
Sport Models	
Size 16	size of place when 16; 1=farm, 2=country, 3=suburb, 4=<50,000, 5=50,001–250,000, 6>250,000 $\bar{x}$ = 3.89, S.D. = 1.78
Region 16	0=nonsouth, 1=south, $\bar{x}$ = .045, S.D. = .207
County Hunting.	hunting licenses per population in county of residence 1975 $\bar{x}$ = .005, S.D. = .007
Parents Owned	parents owned a gun; 0=no, 1=yes; If don't know, value is no $\bar{x}$ = .536, S.D. = .499
Age at First Gun	Years/10, if never owned, value is current age $\bar{x}$ = 3.72, S.D. = 1.94
Trained	Trained to use a gun; 0=no, 1=yes $\bar{x}$ = .450, S.D. = .498
Veteran	military gun use; 0=not veteran—not currently in military, 1=veteran or in military, 2=required to carry a firearm, 3=in combat zone, 4= in combat; respondent or respondent's husband $\bar{x}$ = 1.01, S.D. = 1.45
Hunt	members of the family hunt or shoot together; 0=no, 1=yes $\bar{x}$ = .094, S.D. = .292
Sportmags	Subscribes to *Sports Afield, Field and Stream, Outdoor Life,* or any other magazine especially directed to firearms' owners; number of different magazines $\bar{x}$ = .205, S.D. = .604
Gun for Sport	0=no, 1=yes when final endogenous; −1=no, 1=yes when conditioning endogenous $\bar{x}$ = .179, S.D. = .384

spondent's age when the first gun was owned. If the respondent has never owned a gun, current age is coded. The variable is divided by ten.

Veteran reflects military gun use. Those who have never been in the military get 0 on the variable. All respondents were asked about military service. If the respondent was a married woman and had not been in the military, the questions were asked about her husband. This assumes that married men who had not been in the military are unlikely to have wives who were in the service. It also assumes that veterans' wives are similar to veterans on related variables.

The endogenous variable in the sporting model is gun ownership for sport. It is coded 0, for no sporting gun, and 1, for owning a sporting gun. Respondents were asked how many rifles, shotguns, and pistols they owned. Then each was asked, "For what purpose do you own the firearm(s)?" Respondents were asked this question repeatedly until no additional reason was volunteered. Hence, a respondent could answer both protection and sport for only one gun. To allow for symmetrical relations in the joint probability model, gun for sport is coded −1 for no gun and 1 for gun ownership for sport when it is a conditioning endogenous variable in the gun ownership for protection equation.

Table 2 contains descriptions of variables appearing only in the protection model. CCrime is the score of the respondent's county of residence on a violent crime factor variable (see Bordua et al., 1979). The factor summarizes rates of armed robbery, aggravated assault, and murder for the period 1972 to 1976.

Copcor indicates the respondent's perception of the ineffectiveness of the police and courts in dealing with crime. It is an additive index of two items. Table 2 shows the construction of the index. Scores on the index were divided by ten. Vioexp, Victim, Fear, Racist, Homedef, Vatt1, and Vatt2 were all constructed as additive indices.

The variables Fear and Racist are scaled to yield values under 9.99.

About 18% of the respondents own a gun, whether it be a long gun or a handgun for sport, while about 6.2% own a gun for

Table 2. Description of Variables in the Gun Ownership for Protection Model

Variable Name	Description
Live Alone	0=no, 1=yes $\bar{x}$ = .167, S.D. = .373.
CCrime	Score on violent crime factor for respondent's county of residence $\bar{x}$=.281, S.D.=2.62.
Proximity of Blacks	Blacks in neighborhood; 0=no, 1=yes, nonwhites coded as 1, don't know are assigned 0 $\bar{x}$=.733, S.D.=.827.
Friend	Know men and/or women who own guns for protection; 0=no, 1=yes, don't know assigned to 0 $\bar{x}$=.427 S.D.=.495.
Copcor	Police and courts ineffective; two items combined; people must be prepared to defend their homes or can police do it: 1=police defend, 5=defend self; how important is increasing police patrols in reducing crime: 1=not at all important, 2=not very important, 3=somewhat important, 4=very important; (defend+police patrol)/10, $\bar{x}$=.743, S.D.=.226.
Vioexp	Violent experiences; four variables combined; struck anyone in anger 0=no, 1=yes, had to carry a gun for protection 0=no, 1=yes, had to use a gun for protection 0=no, 1=yes, ever felt a serious physical threat from another person 0=no, 1=yes; (struck+carry, gun+use, gun+physical threat) $\bar{x}$=.647, S.D.=.838.
Victim	Victimized in crime; sum of five variables: robbery 0=no, 1=yes, theft 0=no, 1=yes, breaking and entering 0=no, 1=yes, assault and battery with a fire arm 0=no, 1=yes, assault and battery (fists) 0=no, 1=yes, $\bar{x}$=.996, S.D.=.131
Perceived Crime	Perceived crime rate in county relative to other counties; 5=much higher, 4=slightly higher, 3=about the same, 2=slightly lower, 1=much lower, don't know assigned to about the same $\bar{x}$=.316, S.D.=1.23.
Fear	Fear of crime; sum of three items/10; afraid to walk alone at night within a mile of home 0=no, 5=yes, afraid to be at home at night, 0=no, 5=yes, how important is crime to you 1=not at all important, 2=not very important, 4=somewhat important, 5=very important, don't know is assigned to 3, low not fearful, high indicates fear $\bar{x}$=.765, S.D.=.375.
Vatt1	Violent attitudes index one; sum of five items—approve of a man punching a stranger if the stranger was in a protest march 0=no, 1=yes, was drunk bumped into wife 0=no, 1=yes, hit man's child after child damaged car 0=no, 1=yes, approve of policeman hitting man if man said vulgar and obscene things to policeman 0=no, 1=yes, was a suspect in murder case 0=no, 1=yes, high scores indicate violent attitudes $\bar{x}$=.975, S.D.=1.00
Vatt2	Violent attitudes index two; sum of four items—approve of man punching a stranger if the stranger was beating up a woman 0=no, 1=yes, had broken into man's home 0=no, 1=yes, approve of policeman hitting man if man was attempting to escape from custody 0=no, 1=yes, attacking the policeman with fists 0=no, 1=yes, high scores indicate violent attitudes $\bar{x}$=3.26, S.D.=1.05.
Racist	Racial attitudes; sum of two items/10: laws against black-white marriages okay 1=no, 5=yes, black shouldn't push where they are not wanted 1=strongly disagree, 2=disagree, 4=agree, 5=strongly agree, don't know coded as 3, high scores indicate antiblack attitudes $\bar{x}$=.491, S.D.=.258.
Homedef	Home defense measures, sum of three items: taken special measures such as special locks, burglar alarms, guard dog? 0=no, 1=yes, security was important in choosing home 0=no, 1=yes, keep doors locked in the daytime 0=no, 1=yes, high scores indicate more defense measures $\bar{x}$=1.54, S.D.=.995.
Gun for Protection	0=no, 1=yes when final endogenous −1=no, 1=yes, when conditioning endogenous $\bar{x}$=.062, S.D.=.241.

protection. It is important to note that the gun variables do not measure household gun ownership. They measure the respondent's gun ownership. It is difficult to attach attitudes and motivations to households possessing guns. Attaching the respondent's attitudes or motivations for ownership to the household results in reification and overgeneralization. On the other hand, individuals' motivations for ownership and attitudes can be tied to individuals' behavior (gun ownership) without undue inference.

Analysis and Results: The Sporting Model

In the sporting model, exogenous variables with respect to gun ownership are: Age at first gun, Veteran, Sportmags, Trained to use a gun, and Hunt. Age at first gun, Veteran and Sportmags are estimated using OLS. The remaining equations are estimated using the Nerlove-Press maximum-likelihood logistic response procedure.

Figure 1 shows the final estimated path model for gun ownership for sport. Insig-

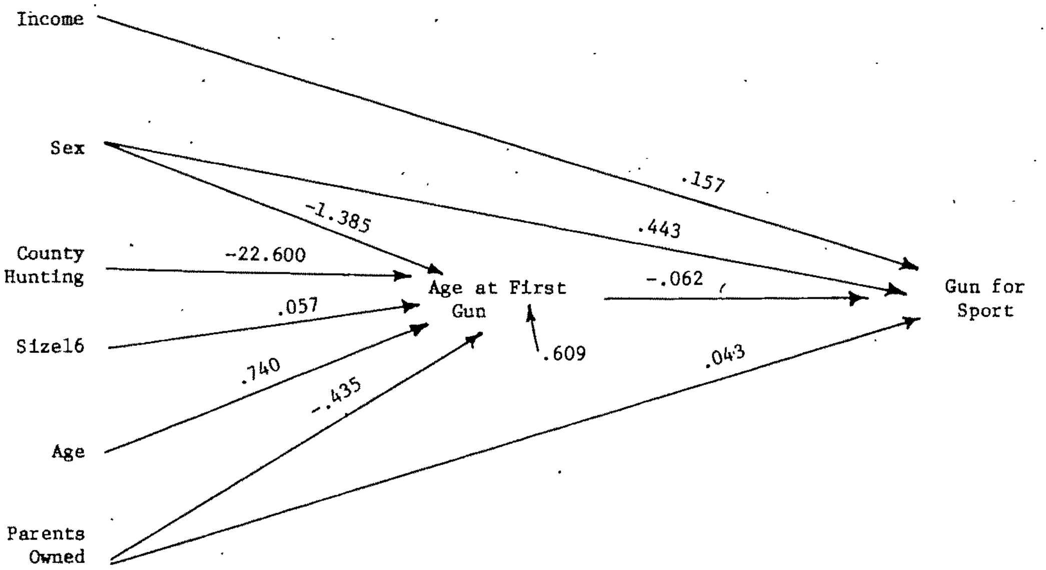

Figure 1. A Path Model of Firearms Ownership for Sport, OLS and Logistic Estimation Procedures Are Used Where Appropriate

nificant variables have been dropped from the model. Income, Sex, Parent's gun ownership, and Age at first gun are the only significant determinants of gun ownership for sport. Sex, Age, County hunting, Size 16, and Parent's gun ownership also have indirect effects on sporting gun ownership. Sex, Parent's gun ownership and County hunting all have positive indirect effects on gun ownership for sport through age at first gun. That is, males, respondents with gun-owning parents, and respondents who live in high hunting counties all tend to be sporting gun owners. Respondents who lived in small towns when 16 years old tend to have acquired their first gun at an early age. This translates into a high probability of gun ownership for sport in later life.

Table 3 shows OLS and Logistic parameter estimates for models of age at first gun and gun ownership for sport. Relations which were not significant at the .05 level of a one-tailed test have been dropped from the model. Equations were reestimated without insignificant relations. Either normal or asymptotic standard errors are in parentheses. The row in the table labeled λ is actually the likelihood ratio statistic:

$$\lambda = -2(\mathrm{LOG}(L(0)) - \mathrm{LOG}(L(\mathrm{OPT}))). \quad (2)$$

The statistic is distributed as chi-square with D.F. degrees of freedom. Significant values of λ indicate that the obtained likelihood function (L(OPT)) is significantly different from zero (L(0)). Hence, the equation is significantly better than an equation with zeros for parameter estimates. All equations reported for both the sporting and protection models are significant.

Sex, Size 16, Age, County hunting, and Parent's gun ownership are all good predictors of age at first gun. Males are younger when acquiring their first gun. The larger the city in which one grew up, the older the age at first gun. Where the county hunting rate is high, age at first gun is low. Finally, if the respondent's parents owned a gun, the respondent is likely to have acquired the first gun at an early age. In short, small town males whose parents owned a gun and who now live in high hunting counties are most likely to have acquired a gun at an early age. The equation explains about 63% of the variance in age at first gun.

Gun ownership for sport is the result of financial status, sex, and the early socialization into gun use. Men are more likely to have acquired a gun at an early age. It is not surprising that they are also more likely than women to own guns for sport.

* Significant at the .1 level one-tailed.

Guns and the sporting activity associated with them are expensive. Higher income respondents find it easier to own a gun for sport. The county hunting rate has dropped out of the picture. Individuals respond more to parent's gun ownership and age at first gun. Respondents tend to own guns when their parents owned guns and when they were young first-time owners. These findings suggest that, apart from the expense of gun ownership for sport, ownership is largely a function of early socialization into gun use.

Parent's ownership is central to relations in the sporting model. This measure of socialization into sporting has a direct effect on age at first gun. It should be noted that the county hunting rate has no direct effects on measures of individual contact among subcultural members such as family gun use and sporting magazines. Its effects are limited to socialization (age at first gun).

This suggests some support for the existence of a subculture of sporting gun ownership. That is, each of the three conditions indicating a subculture of sporting ownership have been met. Significant numbers of people exhibit a behavior which is different from the larger culture—they own guns for sport.[2] Second, we have located the mechanism of socialization into the subculture. The intergenerational transmittance is carried out via family socialization through parent's gun ownership and age at first gun. Third, there are indirect effects of county hunting activity on sporting gun ownership. This is a mild indication of cultural contact in the respondent's area of residence. The subculture appears to be largely, but not exclusively, male. Further, other situational and demographic variables do not appear to be particularly strong in predicting firearms ownership for sport. Neither are they effective in neutralizing cultural variables.

Not all of our cultural variables were effective in predicting firearms ownership for sport. There is no evidence suggesting individuals are socialized into a sporting subculture in the military. Additionally, two indicators of contact among members of the subculture (family hunting and magazine subscriptions) were not effective in predicting sporting gun ownership when parent's ownership and age at first gun were controlled.

---

[2] We do not mean to imply that small numbers of people own guns. While about 20% of respondents over age 18 own a gun, about 50% of families own at least one gun.

Analysis and Results: The Protection Model

We now turn to estimating the model of firearms ownership for protection. Table 4 shows OLS equations for variables in the model which are endogenous with respect to gun ownership for protection. Relations which are insignificant at the .05 level have been eliminated. Equations were reestimated without insignificant variables. The table includes the Logistic equation for gun ownership for protection.

Violent crime in the county is the only significant predictor of owning a gun for protection. Similarly, county crime is the only predictor of friend's owning a gun for protection. This is a good deal simpler than the relations hypothesized. Apparently, in this study, people's defensive ownership of guns is totally a function of violent crime in the area. It is not an extension of a general home defense orientation or a product of any of the other variables in the model, such as violent attitudes or racism.

To this point, there is no evidence of a subculture of defensive gun ownership. While we can locate a group of protective gun owners, there is no indication of contact among them. That is, having friends who own guns for protection does not predict the respondent's protective ownership. Additionally, there is no evidence of a subculture of violence centered on protective ownership. Violent attitudes (Vatt1 and Vatt2) and violent experiences Vioexp) do not predict gun ownership for protection.

A question remains about the effects of family socialization on protective ownership. Two possibilities exist. First, family socialization variables could have direct effects on protective gun ownership. Second, family socialization variables could have indirect effects on protective ownership through sporting ownership. If the latter is the case, a subculture of protection could be accepted on the grounds that both socialization and contact among members occurs through membership in the subculture of sporting gun use. Of course, no such argument could be made for the existence of a subculture of violence centered on protective gun ownership, since violent attitudes and violent experiences do not predict protective ownership.

In essence, we want to evaluate whether or not there is a joint probability of occurrence between firearms ownership for sport and firearms ownership for protection. One way to attack this problem is along the lines suggested by Nerlove and Press (1973). That is, by applying maximum-likelihood methods to the univariate dichotomous logistic response function in symmetric form to approximate full information, maximum-likelihood estimates of the joint probability function.

Table 5 shows the equations for gun for sport and gun for protection estimated in this way. All variables which were significant in either equation individually are included in the conditional estimation equations. For symmetry, the conditioning endogenous variable is coded -1, for no gun, and 1, for gun. For example, the gun for protection equation answers the ques-

could not argue that contact among members of a protective subculture and socialization into the subculture are provided by a subculture of sport. Additionally, Table 5 shows that family socialization variables do not have direct effects on gun ownership for protection. Hence, protective ownership meets none of the conditions necessary for a subculture of protective ownership to exist. In fact protective ownership responds only to a situational variable—the county crime rate. The conditional model is abandoned for the simple independent equations of Tables 3 and 4.[3]

---

[3] There is a final matter of concern. One might be tempted to argue that some of the respondents in the

Other Findings in the Protection Model

While only one variable was significant in predicting protective firearms ownership, some consideration should be given to the pattern of relations among the remaining variables in the model.

The perceived ineffectiveness of the police and courts (Copcor) is determined by three variables. They are: whether or not the respondent lives alone, the respondent's education, and race. Blacks and those with low education see the police and courts as being ineffective in dealing with crime. Those who live alone tend to think that the police and courts are effective in dealing with crime.

The respondent's perception of the level of crime is not solely a function of the acutal crime rate in the county. Perceived crime also responds to the proximity of blacks and to victimization. The data suggest that the presence of blacks is used by people to indicate the level of crime. Similarly, respondents who have been victimized perceive more crime in their county of residence.

The data suggest that the fear of crime is founded in reality. It responds to eight variables. They are Sex, Income, Education, Size, Proximity of blacks, Victimization, Copcor, and Perceived crime. Women are more likely to be afraid of crime than men. Those with low income and education are also more likely to fear crime. City life leads to a fear of crime, as does having blacks in one's neighborhood. Apart from this, those who have been victimized, those who see the police and courts as ineffective and those who perceived high crime in their county are more afraid of crime.

People defend their homes when crime becomes a threat. Education, Race, Size, County crime, Victim, and the Fear of crime are all significant determinants of home defense. Poorly educated people and blacks tend to have a strong home defense. Those who live in larger cities tend to be more concerned with home defense. Similarly, the higher the county violent crime rate, the greater the home defense. If the respondent has been victimized, home defense increases. The greater the fear of crime, the greater the home defense. Figure 2 shows the estimated path model. Vioexp, Vatt1, Vatt2, and Racist had no significant direct or indirect effects on home defense and gun for protection. Therefore, they have been dropped from the model.

Figure 2 shows that there are negative direct and indirect effects of education on home defense measures. These indirect effects pass through Copcor and Fear. That is, highly educated people see the police and courts as effective, and, hence, they are less afraid of crime and less likely to take home defense measures. Presumably, those with high income can afford to live in neighborhoods where they have no reason to fear crime. Hence, they find no need for serious home defense measures.

The same general logic is true for race. Blacks think that the police and courts are ineffective in dealing with crime, and blacks are more likely to be victimized in crime. This leads to a fear of crime, and, subsequently, to a home defense orientation.

Because women fear crime they are more likely to take home defense measures. On the other hand, men are more likely to have been victimized and, therefore, to take home defense measures. The indirect effect for women is $-.163$, while for men it is .016. Adding the indirect effects of sex on home defense,

$$.016 - .163 = -.147 \tag{3}$$

shows that women are more likely to take home defense measures.[4]

The young are more likely to have been victimized, and, therefore, to take defensive measures. The proximity of blacks has indirect effects on home defense

---

criminal, the .953 estimate is probably high. One gun criminal lying about gun use probably would not seriously affect the parameter estimates in the models.

[4] Since the modified logistic response model differs in functional form from OLS, extreme caution should be used in evaluating indirect effects between logistic and OLS equations. In this example, both are OLS equations. However, when estimation is mixed, the precise nature of indirect effects depends on the predicted values (P(x)) for both equations, and not solely on the value of coefficients.

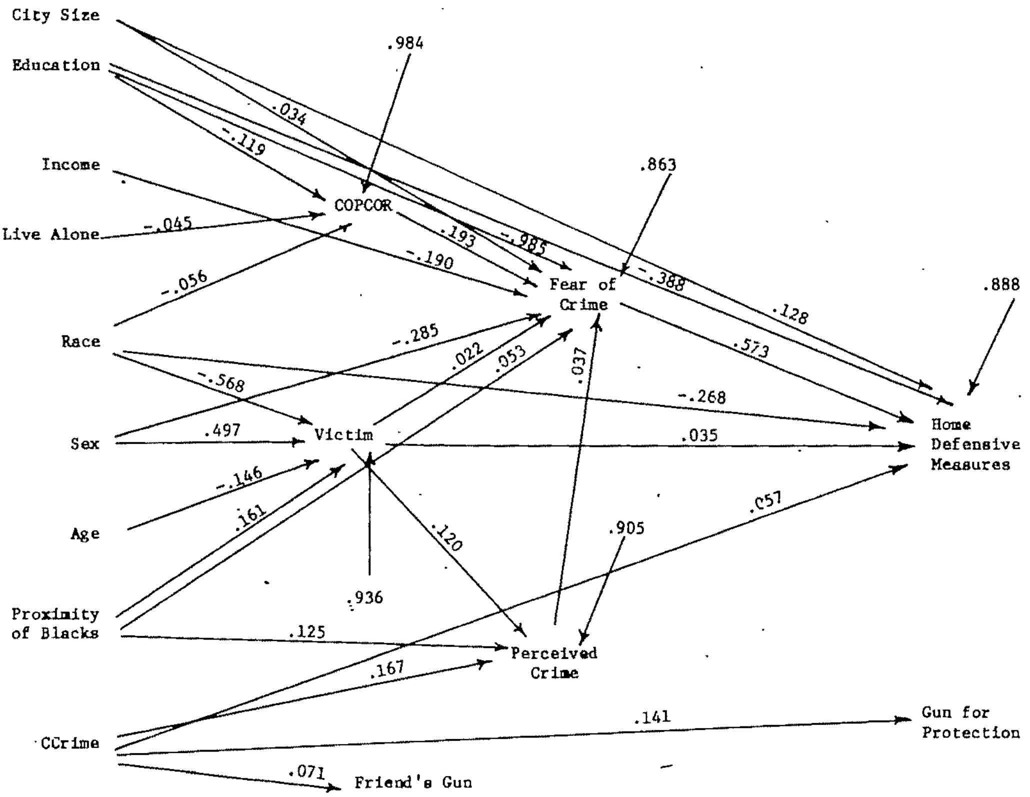

Figure 2. A Path Model of Firearms Ownership for Protection, OLS and Logistic Estimation Procedures Are Used Where Appropriate

through victimization, perceived crime, and the fear of crime.

Having blacks in one's neighborhood leads to victimization and high perceived crime. This results in the fear of crime and a home defense orientation.

Summary

There is no doubt that socialization plays a strong role in the sporting use of guns. Parent's gun ownership and age at first gun were both strong predictors of owning a sporting gun. Further, one indicator of contact among members of the subculture did relate to gun ownership for sport. That is, the county hunting rate has indirect effects through age at first gun on firearms ownership for sport. These findings support the notion of a subculture of sporting gun use.

Not all of the subcultural indicators were significant predictors of firearms ownership for sport. Several studies have found a strong relation between veteran status and firearms ownership (see Newton and Zimring, 1968). This relation was proven spurious. Veterans are no more likely than others to own guns because of their military training. Similarly, neither family hunting nor sporting magazine subscription are good measures of contact among individuals owning firearms for sport.

Gun ownership for protection is a more straightforward phenomenon than hypothesized. Gun ownership for protection is only related to situation. That is, violent crime in the county of residence is the only significant predictor of gun ownership for protection. Firearms ownership for protection had none of the trappings of a subculture. We found no evidence of socialization into the subculture, and, hence, no evidence that the behavior is transmitted intergenerationally. Similarly, we found no evidence of contact among indivudals who own guns for protection. Additionally, we found no indication of overlap between a subculture of sporting gun use and ownership for protection.

Since violent attitudes and violent experiences did not predict gun ownership for protection, we must also reject the notion of a subculture of violence centered around protective ownership. We do not mean to imply that this is conclusive evidence that protective gun-owning subcultures do not exist. Other measures of socialization into the subcultures, of contact among members of the subculture, and of violent attitudes and experiences may be good predictors. However, this study provides no such support. A subculture of protective ownership was not found to be independent of situation.

Nor do we mean to imply that a myriad of situational and demographic variables were capable of predicting protective gun ownership. Neither an unrealistic fear of crime nor the perceived effectiveness of the courts and police affected protective ownership. This implies that convincing people that they are safe and that the courts and police will protect them would not reduce gun ownership for protection. Protective gun ownership was not found to be a logical extension of a home defense orientation. There is no sex difference in the probability of ownership for protection. Unlike sporting ownership, women are as likely as men to own a gun for protection. Racist attitudes did not predict owning a gun for protection. Similarly, age, size of place, income, living alone, and the proximity of blacks were all insignificant in predicting gun ownership for protection. Victimization did not play a role in owning a gun for protection. Additionally, the perceived crime rate is of little consequence. The only predictor of owning a gun for protection is living in the context of high crime. The policy implication is obvious. In order to reduce the demand for protective guns we must reduce the crime rate.

THE TACIT CONVENTIONS OF THE MODERNITY SCHOOL: AN ANALYSIS OF KEY ASSUMPTIONS*

WILLIAM C. RAU
State University of New York, Albany

American Sociological Review 1980, Vol. 45 (April):244–260

This paper examines a number of conventions which guide current research into psychological modernity. The key assumption is unidimensionality, an assumption which underlies recent investigations into the convergent and discriminant validity of various modernity scales. I show that this assumption takes for granted what needs to be proven and, therefore, violates the null hypothesis axiom. Using data from a five nation study of individual modernity, I statistically examine this assumption and demonstrate its inappropriateness to modernity research. I close with an interpretation of patterns of modernity in the five nations. These patterns have been derived from factor solutions that meet statistical tests of dimensionality. The results suggest that existing modernity data should be reanalyzed.

> You may . . . find much of the thinking of an individual, a school, or even a generation, dominated and determined by one or another turn of reasoning, trick of logic, methodological assumption, which if explicit would amount to a large and important and perhaps highly debatable proposition in logic or metaphysics. (Arthur O. Lovejoy, 1936:10)

INTRODUCTION

Every paradigm is rooted in a number of tacit conventions and shared convictions that constitute unarticulated boundaries to research within a scientific community. So it is with the modernity school. Generally not recognized or explicitly formulated, these conventions often tell us more about the nature and developmental stage of a theory than would an examination of either the logic or evidentiary basis to the theory. These assumptions can act as barriers to the use of methods required to render a theory testable. As a result, they can assume the additional disfunction of masking anomalies between evidence and theory. Finally, their habituation in re-

I am grateful to Bernard Karsh, Frederick Fliegel, William Form, Ken Southwood, Reeve Vanneman, and to Jere Cohen, Mariah Evans, Joseph Kahl, Wilbert E. Moore, Allan Schnaiberg and an anonymous reviewer for commentary on several versions of this paper. I would like to thank Ledyard R. Tucker for bringing the parallel analysis criterion to my attention.

search practice can obstruct the resolution of anomalies once they occur.

This state of affairs characterizes modernity studies. The purpose of this paper, therefore, is to raise several unexamined assumptions of this school to the level of explicit propositions. I then demonstrate that the leading assumption in modernity research violates one of the basic principles of scientific jurisprudence and, moreover, is unnecessary in research. Further, this assumption cannot withstand statistical examination. The assumption is unidimensionality. The main purpose here is to reveal the inappropriateness of this cardinal assumption and the problems which flow from it. I do this first by examining how unidimensionality handicaps research into individual modernity. I, then, marshal evidence which shows that modernity studies must move to a multidimensional perspective if the field is to remain viable and dynamic.

Some of the assumptions of the contemporary modernity school can be seen in the work of Cohen and Till (1977) and Armer and Schnaiberg (1972; 1975; 1977). This is ironical since the latter are among the more articulate critics of the assumptions of unidimensionality and unilinearity in modernization theory. Even so, their classic review of modernity scales operates within a unidimensional framework. They are, therefore, confined within the limitations of the style of research they criticize. The major problem is that they reveal serious inadequacies in modernity scales but are unable to suggest solutions to the resulting impasse.

One of the primary objectives of both investigations is to determine whether modernity scales meet the convergent/discriminant validation test (see Campbell and Fiske, 1959). Unfortunately, because this is an advanced validation procedure, the resulting evidence misdirects attention from fundamental deficiencies in the construction of the scales which go into the test. These investigations assume that the study of modernity has advanced beyond an exploratory research stage; hence, antecedent and more primitive questions are overlooked.

The central question can be stated simply. Is individual modernity unidimensional or multidimensional? A number of scholars, such as Portes (1973) and Schnaiberg (1970b), suggest the latter, a position which receives statistical support in this paper. Under such circumstances, the varied operationalizations of individual modernity (as reflected in the classes and types of items in modernity batteries) cannot be assumed to measure only one set of values. Yet the conventional method of creating scales from such batteries uses item analysis as a "blind culling procedure" (Lumsden, 1978:23). As Schnaiberg (1976a; 1976b) and Armer (1977) note recently, the resulting scales cannot be expected to be either valid or equivalent. In retrospect, they used the convergent/discriminant validation technique when every scale in the convergent class was probably invalid from the start. This suggests that we return to the logically antecedent problem of scale construction.

The principles of scale construction require that one should first consider the construct and content validity of items going into a scale before conducting statistical tests of reliability and validity. However, as Nunnally (1967:79–88) and Lord and Novick (1968:350–1) point out, the logically and temporally prior process of conceptual validation is generally not considered, or is explored after a scale is constructed. (Analogous problems have been encountered in the natural sciences. See Kuhn, 1961). Instead, a number of scholars working in a common area develop different measures for the same thing, conduct research, and publish results. Findings accumulate and contradictions begin to surface. This precipitates questioning on the validity and conceptual framework of the various measures being used. Practitioners are then forced to deal explicitly with problems of construct and content validity. This sequence of events describes the current state of modernity studies. Consider the question of convergent and discriminant validity in Armer and Schnaiberg (1972).

Validation Procedures

In terms of modernity theory, convergent validity assumes that if

$$M_1 \cap M_2, \text{ then } M_1^* \cong M_2^*,$$

where M_1 and M_2 represent conceptual articulations of the traditional/modern dichotomy, and where M_1^* and M_2^* represent a sample of measures of each conceptual elaboration. If the two scales are conceptually equivalent, then, empirically, they should behave in a similar fashion with scores of individuals correlating highly. Discriminant validity assumes that if

$$M_1, M_2 \not\subset A, \text{ then } M_1^*, M_2^* \neq A^*,$$

where M and A represent conceptually distinct value domains, and M* and A*, a sample of measures for each concept.

Thus, the test that Armer and Schnaiberg, 1972, conduct, and that Cohen and Till, 1977, replicate with modification is that

$$rM^*_1M^*_2 > rM^*_1A^*, rM^*_2A^*.$$

Put simply, the correlation among the modernity scales should be substantially higher than the correlation of modernity scales with the measure of another concept. This is a sound testing strategy that can be considered for any additive construct.[1] A prior question, however, is whether the assumptions of the test have been met. Specifically, are the scales used in both reports suited to tests of convergent and discriminant validity? The answer is no.

CONCEPTUAL EQUIVALENCE AND DISSIMILARITY

Consider the modernity scales. These scales are extracted from modernity batteries developed by Smith and Inkeles (1966), Kahl (1968), Schnaiberg (1970a), and Armer (1970). In what sense are the sets of measures in these batteries conceptually equivalent? On either a conceptual or empirical level, are they sampling from the same value universe? Witness, in Table 1, the value sets or subscales contained in these batteries.

The degree of overlap for the number of items, the number of value subsets, and thematic content of value subsets is low. This table also illustrates that the reservations of Cohen and Till (1977:374–5) regarding the inclusion of the Schnaiberg Emancipation Scale in validation tests are well taken.[2] In addition, the Kahl Modernity I Scale is quite different from the Smith and Inkeles and Armer indices. Even if we discard subscales 13 to 17 (from Stratification of Life Chances on), the equivalence of the Kahl, Smith and Inkeles, and Armer modernity batteries is more apparent than real. Smith and Inkeles's Political Identification/Activism Subscale, for example, has no direct equivalent on the other batteries. Similarly, Kahl's Individualism Subscale shares an affinity with the Receptivity to Change Subscales only on a highly abstract, conceptual level.

Finally, the degree of equivalence of

---

[1] Not all test theorists think so. Lumsden (1976), for example, feels that this procedure is too difficult in practice and unlikely to yield reasonable dividends. In his (Lumsden, 1976:270) words, "the multi-trait multi-method procedure seems to require that a test have an identical twin of the opposite sex." Moreover,

> where great care has been taken to test construction, where much is known a priori about traits, methods, and relationships between them, the validation procedure will more and more resemble construct validation and the explicit setting up of the multi-trait multi-method matrix will be rare.

This is no doubt correct, insofar as it goes. From the perspective of comparative measurement, however, this technique may assume new functions. One of the central problems in cross-national study concerns the relation between sets of culture common and culture specific measures of the same concept (see Triandis et al., 1971; Rau, 1979:169–201). This problem goes to the heart of the disagreement between Inkeles (1969) and Stephenson (1968;1969). Here, the multitrait, multimethod procedure provides a way to deal with the questions raised in this exchange. It gives us a systematic approach to investigating linkages between the particular and general aspects of cultural forms. At this level of analysis we are not looking for identical twins, but family relationships.

[2] In addition, Schnaiberg's battery consists of behavior items rather than attitudinal statements. As presented elsewhere (Rau, 1979:29–60, 256–76), and as Armer and Isaacs (1978) have demonstrated, modern values—at least as portrayed by an overall modernity index—are not sufficient for the prediction of behavior. On the other hand, the underrepresentation of items dealing with women's emanicipation in most modernity studies means that Schnaiberg's battery may prove to be helpful in an exploratory analysis of the nature and number of latent traits which should be given attention in modernity studies.

many of the subscales is often a function of the same concept labels rather than content equivalence of subscale items. A case-in-point concerns one of the more comparable subscales, namely, the religiosity subscales in the first three modernity batteries. The items within each subscale are as follows:

Kahl

(Help from God/hard work by people) most important for the country's future.
(More religious/less religious) than father.
I consider myself (very/not very) religious.
In the last two months, I went to church (often/not often).

Armer

Should give alms to the poor because of (fear of God/compassion).
Should follow (religious men/sacred books/ own conscience).
(Need not be/should be) respectful of other religions.
A boy (cannot/can) be truly good without any religion.
Heaven is for (own religion only/good people of other religions).

Smith and Inkeles

Who do you admire most? monk/both/ factory owner.
Who has done more for this country? monk/ both/factory worker.
Most important in caring for sick person: prayer/both/medical care.
Can a man be good without religion? yes/no.
A man should give to the poor because of: fear of God/generosity.

Each set of items probably taps the same religiosity/secularism domain and is likely to produce statistically equivalent scales. Nonetheless, without empirical confirmation that these items covary together, a skeptic could argue that Kahl's scale is a religious participation scale, Armer's, a religious tolerance scale, and Smith and Inkeles's, a religious esteem scale.[3]

---

[3] A more important difficulty is that these scales do not discriminate among types of religiosity and secularism, or among the ethical precepts of the great religious traditions. A devout Hindu, Muslim, or Protestant could receive the same scores on these

Due to these considerations the conceptual and statistical equivalence of modernity indices is a question that deserves detailed and systematic attention. One can argue that existing modernity scales are not conceptually equivalent. Present methods of scale construction, in conjunction with the unsystematic diversity of value sets and attitudinal statements in the various batteries, cannot be expected to produce scales which are either equivalent or valid. If these scales are not conceptually equivalent, then a test of convergent/discriminant validity is illogical.

Subset equivalence of modernity indices. There are, however, several thematic cores across these modernity batteries. The unique virtue of the Armer-Schnaiberg Uptown data set is that it allows factor analysis within and across these batteries. It will, therefore, prove invaluable in the validation of the attitudinal content and number of value themes appropriate to the modernity concept.

I have conducted a somewhat analogous investigation into the structural characteristics of the Peshkin modernity battery used in the Karsh five nation study of value modernization (see Rau, 1979:169–201). This analysis establishes efficacy-activism as a pancultural value theme for the nation samples in this study. We have, therefore, provided support to the observations of Kahl (1968) and Inkeles and Smith (1974) on the centrality of personal efficacy and activism in modern value systems. In terms of their interpretation, efficacy establishes that an individual can and should control and direct his own destiny, and stresses the role of certain values and behaviors in achieving chosen ends. Activism establishes that an individual feels that men in general can and should harness and direct natural and social forces. The two are mutually reinforcing and very close conceptually and psychologically.

The measures used to establish discriminant validity are anomia, alienation, and SES. Here the value orientations are substantially more restricted than in the case of overall modernity. Moreover, SES is a structural index rather than a measure of values. Thus, the tests of discriminant validity are based on a subset to set comparison. If

$$A \not\subset | M, \text{ then } A^* \neq M^*,$$

where A is the value subset that is conceptually distinct from all the values incorporated in the set M.

Anomia/alienation and efficacy/activism. A difficulty arises, however, when we look at anomia and alienation and then consider their putative distinctness in relation to the modernity concept. As mentioned, the core value set in modern value systems appears to be efficacy/activism. Anomia and alienation, in turn, represent measures of personal powerlessness, normlessness, the lack of an internalized and integrated value system and, in general, a sense of personal futility and societal fatalism. Thus, on a conceptual level anomia/alienation are mirror-opposites, inverted equivalents, to personal efficacy and activism.

To illustrate this point, items from Srole's (1956) Anomia, Middleton's (1963) Alienation, and Kahl's (1968) Modernity Battery are comingled in Table 2. At first glance, it is difficult to identify the source of each item, and even more difficult to establish a rationale for the conceptual distinctness of the separate groups of items. It strains credulity to assume that a panel of lay judges could make the necessary distinctions, and even with such virtuosity one would find it hard to demonstrate a convincing logic of exclusiveness. In short, the primary difference between anomia/alienation and personal efficacy/activism is the direction in which one

---

scales. Hence, the meaning of scores can change from one cultural and religious context to another. The comparative usefulness of such measures is quite limited.

Another quandary concerns the relation between mundane values and religious belief. We cannot assume a consistent relationship across components in modern value systems and the beliefs of different religions. It is, thus, unfortunate that Charles Morris's (1955; 1956) work on the cross-national analysis of ethical systems appears to have been overlooked by modernity scholars. A simplified version of his Ways of Life questionnaire may provide us with the type of instrument needed to separate out different ethical points of view and their relation to religiosity/secularism and the various modern value orientations.

Table 2. Srole's Anomia and Middleton's Alienation Items Intermingled with Key Items from Kahl's Attitudinal Battery

Number	Statement
1	It doesn't make much difference if the people elect one or another candidate, for nothing will change.
2	There is not much I can do about most of the important problems that we face today.
3	There's little use in writing to public officials because often they aren't really interested in the problems of the average man.
4	Nowadays a person has to live pretty much for today and let tomorrow take care of itself.
5	With things as they are today, an intelligent person ought to think only about the present, without worry about what is going to happen tomorrow.
6	Things have become so complicated in the world today that I really don't understand what is going on.
7	The secret of happiness is not expecting too much out of life, and being content with what comes your way.
8	In spite of what some people say, the lot of the average man is getting worse, not better.
9	People in a big city are cold and impersonal; it is hard to make new friends.
10	These days a person doesn't really know whom he can count on.
11	I often feel lonely.
12	Most people will repay your kindness with ingratitude.

scores responses. Since the same sort of items masquerade under different exterior labels, the high negative correlations between anomia/alienation and measures of modernity are primarily a reflection of the difference in the way the two classes of scales are scored.

In other words, anomia and alienation, as negative expressions of efficacy and activism, lie in inverted form at the very center of the various modern value syndromes. Anomia, alienation, efficacy, and activism items all represent expressions of the same underlying trait. Thus, in this instance:

$$A \subset M1, M2.$$

This means that the middle term which links these semiequivalent modernity scales is represented as the discriminant validation index. Hence, the common empirical core which unites these rather different indices is being used as the distinct concept measure.[4]

SES and modernity: discriminant or predictive validity? The use of SES as a measure of discriminant validity is also questionable. SES is, in large part, a measure of privileged access to institutions, namely, the extent to which individuals have access to, have been processed through, or participate in complex, rationalized organizations, such as institutions of higher learning or bureaucratized and highly capitalized work organizations. Now, modernity theory clearly states that such institutionalized milieux have strong modernizing effects (see Form, 1976; Kahl, 1968; Inkeles, 1960; 1975; 1976; Inkeles and Smith, 1974; Stinchcombe, 1974). For example, Kahl (1968:45–52) observes that SES is one of the more powerful predictors of modernity, and that the results of his study indicate that "a modern perspective diffuses through society via the social-class hierarchy." Additionally, Inkeles and Smith (e.g., 1974:133–43) have established that the institutional components of social class indicators (for example, educational attainment) influence the development of modern values independently of the other correlates of social class. A theory of psychological modernization that incorporates both institutional and social learning perspectives cannot also argue that modernity is a class-free concept. Since class is closely related to both institutional privilege and differences in socialization practices and educational attainment, some association is inevitable. From this perspective SES must be seen as a measure of predictive, not discriminant, validity. The positive correlations between SES and modernity indicate that the latter does result in theoretically predicted and meaningful differences among social groups.

---

[4] On logical and psychological grounds it is difficult to assume that an individual could be both alienated and activist in his values. Instrumental activism represents the negation of psychological expressions of alienation. Hence, measures of the two concepts should emerge as polar ends framing the same continuum or latent trait. If so, it is proper to represent these in a fashion somewhat analogous to Parsons's construction of the pattern variables. An actor can be either alienated or activist in his values, but he cannot be both at the same time. Thus, in terms of their empirical constitution, measures of these linked conceptual dichotomies should cluster on opposite ends of the same factor.

The use of SES in a test of discriminant validity mixes a real concern regarding spuriousness with the requirements of scale validation. Most modernity theorists assume that this value system will contribute to the total explained variance in a causal model. Thus, while social class variates will be instrumental in the inculcation of modern values, these values, in turn, will condition outcomes further along in a causal chain. It is, therefore, necessary to establish that the relation between values and other social phenomena is not a spurious function of social class. But the intermediate location of values in any causal chain does not rule out a strong relation between class and values. Thus, the comparison of social class and modernity in a test of discriminant validity is illogical.

Dimensionality and Scale Construction

Since the importance of dimensionality is not immediately obvious, its relation to scale construction needs emphasis. When constructed properly, a scale measures a single underlying trait or psychological process. The items in the scale will, therefore, covary more highly with each other than with measures of other traits. Under such circumstances a scale will possess unidimensional properties and will tend toward factorial simplicity. Hence, the importance of dimensionality. If a scale is factorially complex, then independent variation across items in the scale cannot be ruled out. Such scales may measure more than one property or latent trait. This goes against the very principle of measurement since the latter

> implies that one characteristic at a time is being quantified. The scores on an attitude scale are most meaningful when it is known that only one continuum is involved. Only then can it be claimed that two individuals with the same score or rank order are quantitatively and, within limits, qualitatively similar in their attitude toward the given issue. As an example, suppose a test of liberalism consists of two general sorts of items, one concerned with economic, the other with religious issues. Two individuals could thus arrive at the same numerical score by two quite different routes. Now, it may be true that economic and religious liberalism are correlated but, unless highly correlated, the meanings of scores based on such a composite is questionable. (McNemar, 1946:298)

In such situations, results derived from factorially complex scales—designated conglomerate measures by psychometricians—are likely to contain major errors.

Now, a strange inconsistency. Many modernity theorists assert that psychological modernity is multifaceted, complex, and multidimensional. Why, then, the resort to "blind culling procedures," like item analysis, to select scale items from batteries which contain measures for as many as 24 different value themes? As stated, the basic characteristic of any multidimensional phenomenon is independent variation across the properties which constitute the phenomenon. The reason we compartmentalize a multidimensional entity into its constituent traits is to avoid the problem of scale aggregation. If we bury separate properties or latent traits within one index, then independent patterns of variation are concealed or "washed out" in the aggregate index. As a result, we can distort and obfuscate potentially important distinctions required in the precise specification of psychological and social processes.

In the final analysis, the unidimensional scalability of overall modernity is an empirical question that is answerable with fair precision by means of a number of statistical tests. Yet, present investigations into modernity scales have not considered such tests even though this problem bears directly on the issue of convergent and discriminant validation. This is particularly apropos to comparative studies since the potential for the errors associated with conglomerate scales is likely to be magnified when different national and cultural areas are under study. As such, scale aggregation can conceal both national differences and similarities. One outcome can be scores which are epiphenomena of masking statistical techniques rather than human patterns of valuation.

The Modernity Debate and Unidimensionality

Dimensionality is important because of the aforementioned problems. It also opens inspection of a number of questionable research practices. In terms of methodological conventions, three subsidiary issues are tied to this assumption: (1) the general reliance on item analysis to develop scales; (2) the relation between reliability coefficients and itemetric scales; (3) the lack of a statistical test of dimensionality due to the reversal of null and alternative hypotheses in modernity research.

Item analysis. Item analysis has been used to select those items that have acceptable correlations (e.g., where r > .20) with a composite index formed from the sum of all of the items in a battery. The items above the cutting point are used to construct scales and calculate reliability coefficients.

The limiting factor in modernity research is that item analysis was intended for the empirical validation of scales. It does not speak to the theoretical or psychological integrity of the domain sample in the analysis. It assumes that sample items have been predetermined to be valid measures of one target domain or latent trait. These items, in their entirety, should give the boundaries of the construct.

A crucial issue which Armer and Schnaiberg raise concerns the psychological integrity of overall modernity constructs, namely, whether modern value orientations can be represented by a single index. Unfortunately, item analysis cannot provide statistical verification of such a construct. Even if such a construct does exist we do not know the types of modern values which define this construct. Lacking this information, we cannot classify specific measures or value sets into an overall modernity category. Hence, several difficulties crop up when items of unknown construct validity are chosen by this technique. First, it is virtually impossible not to establish a number of item-to-scale correlations of acceptable magnitude. Item analysis, Guttman (1971:343) observes, is widely used because "it is virtually guaranteed to succeed for the kinds of data concerned." As a result, item analysis "does not test any hypothesis of scalability. It assumes that scalability exists and that its task is merely to cull out inappropriate items." Once one establishes a sample of items to represent a homogeneous value universe, item analysis becomes an efficient tool for selecting effective scale items. Used appropriately, it can produce scales that are parsimonious, discriminating, and reliable. It cannot, however, establish unidimensionality or conceptual homogeneity.

The reason, and second limitation, is that item analysis does not consider the structure of intercorrelations among measures, thereby begging the problem of dimensionality. The fact that a number of attributes covary with a scale does not mean that they also covary with each other. For example, the fact that activism and secularism items are selected for an itemetric scale only means that the chosen items covary with the aggregate scale. Their relation to each other is unknown and problematic. Unless there is an accumulated fund of knowledge regarding the content and construct validity and statistical characteristics of a psychological domain, one cannot rule out substantial independent variation across measures selected by item analysis. This is particularly apropos to exploratory research ventures such as comparative value analysis. To wit, all value scales should contain statistically interrelated items. This can be established when items in a conceptual class factor together in a factor solution with negligible residuals.

Reliability coefficients. Reliability coefficients do not resolve the aforementioned problems since heterogeneous, factorially complex scales can still produce acceptable coefficients (Cronbach, 1951; Cattell, 1964; Lumsden, 1961; 1976; Nunnally, 1967). Conventional reliability coefficients only establish the strength of the average intercorrelation of the scale items. They assume that low intercorrelations are randomly dispersed among items and that unidimensionality characterizes the structure of intercorrelations. As a result, reliability coefficients, such as the Kuder-Richardson Formula 20, can yield "a gross underestimate of reliability unless the test is unidimensional" (Lumsden, 1976:266). In sum, the fundamental assumption of classical reliability theory is that one general factor dominates the items in a scale (Cronbach, 1951; Cattell, 1964; Cattell and Tsujioka, 1964; Cotton et al., 1957; La Forge, 1965; Taylor, 1977).

Neither item analysis nor reliability coefficients can establish that all items in a scale systematically covary with each other. In this sense, both reliability coefficients and item analysis rely on the same assumptions. Both assume scalability and unidimensionality without verification of either assumption. A more conservative and rigorous approach is first to demonstrate scalability by establishing that the items going into a scale hold a statistical relationship to each other—for example, through a sequential unfolding process or through mutual covariation. On an item-to-item level of analysis one can convincingly establish that a scale has ostensive statistical properties. The nature of this problem is perhaps best illustrated by an example.

At a preliminary stage of investigation, reliable, item analysis scales were developed for the nation samples in the Karsh (1971) project. Each of these scales incorporated both activism and secularism items. Exploratory factor analysis, however, established that items in these value sets loaded on different factors in four of the five nation samples. As a result, we could not assume that the two subsets varied together. Additional analysis confirmed this suspicion. Table 3 presents a case in point.

These results establish that the American and Japanese samples receive nearly identical scores on overall modernity indices. For both samples, however, factor analysis establishes that the two major components in these indices can be represented as separate traits, and therefore as activism and secularism scales. The scores on these scales are quite different. The United States sample is substantially higher on the activism scale and dramatically lower on the secularism scale. As a result, the two nations locate in completely different spaces in a two dimensional matrix.

Table 3. Mean Scores on Overall Modernity, Activism, and Secularism Scales for the Japanese and United States Samples: Scales Adjusted to a 0–100 Range

Nation Sample	Overall Modernity	Activism	Secularism
Japan	59	57	58
United States	57	67	31

In this case, overall modernity indices are conglomerate measures with a serious problem of scale aggregation. Because of such possibilities, psychometricians have insisted that a scale measure one, and only one, clearly defined trait unless there is a well-established rationale for a multiple trait scale. The problem is that the interpretability of scores becomes quite hazardous for such scales.

Thus, if the structure of covariance of modernity batteries is best represented by a multiple factor solution, then the construction of overall modernity scales is highly questionable. It would suggest that subscales collapsed into a one-dimensional index be represented as components or vectors within a multidimensional framework. It would also suggest that current modernity indices are conglomerate measures and, therefore, of dubious utility. With this in mind we turn to the cardinal assumption of the modernity school.

Null and Alternative Hypotheses in Modernity Research

Why has unidimensionality been given the status of an axiom when it should be considered a testable proposition? "The dimensionality of data," Guttman (1971:343) states, "is an empirical phenomenon and not to be determined by fiat." Yet, this is exactly what has happened in modernity studies.

This tacit convention reverses the logic of hypothesis testing. It posits unidimensionality as the null hypothesis and multidimensionality as the alternative hypothesis. For example, Inkeles and Smith (1974:84) frame the question in terms of "whether individual modernity [is] a general syndrome rather than mere congeries of discrete elements." This is both a false dichotomy and an example of the reversal of null and alternative hypotheses. The proper question is not whether modernity is a general syndrome or nothing at all. Rather, the questions are: What are the major value themes which receive expression in a population? What relationships exist among these value themes? and What method of statistical representation is required to portray the patterns of variation within and across these themes?

Given our knowledge of the multiplicity and mutability of values, and of the variety of human undertakings in contemporary societies, scientific prudence dictates that we establish the multidimensionality of values as the null hypothesis. A historical analogue to the present dilemma in modernity studies can be seen in the initial attempts of psychologists, such as Charles Spearman, to represent intelligence by means of a single factor. In fact, Spearman's factorial procedures did not permit the representation of group factors or the multiple factor representation of intelligence (e.g., Thurstone, 1931; 1947; Brody and Brody, 1976). On the basis of his theoretical predisposition and statistical approach, Spearman was both unwilling and incapable of exploring the possibility of a multidimensional structure to intelligence. "This is a most unusual status to give to a revolutionary hypothesis," Guttman (1971:344) notes. He continues: "The whole idea of null versus alternative hypothesis . . . is to have the new kind of idea be the alternative. . . ." Thus, new ideas are not given plausible status without solid, cumulative evidence. Since "intelligence has been recognized by most people to comprise a very complex phenomena [, it] is a new idea to hypothesize a small number of factors." In short, the principle of verification requires that the null hypothesis state that the statistical representation of intelligence requires a large number of factors, "and only the alternative should be a small number, with the one-dimensional case being the extreme alternative."

The null hypothesis, I entertain, is that modernity is multidimensional and nation specific. I assume that the dimensionality, structure of variance, and patterns of meaning expressed in factor matrices will differ across nations and economic and cultural areas. Acceptance of either an overall modernity syndrome or pancultural value themes is, therefore, contingent upon the use of dimensionality criterion tests and factor comparison procedures. The importance of dimensionality estimation is that the tests now available can indicate when a one-dimensional index is statistically acceptable. Recent developments in factor analysis clarify this point.

Tests of Factorial Dimensionality

A common misconception views factor analysts as statistical luddites who smash meaningful constructs into an unwieldy and disorderly mélange of subcomponents. This misconstrues the mathematical characteristics of factor analysis. When used properly, this class of techniques can help to identify the common pattern or patterns of covariation in a correlation matrix. The resulting dimensionality is a function, not of factor analysis, but of empirical patterns in the data under scrutiny. If a set of attitudinal measures is characterized by unidimensionality, then one, or, at most, a few factors should represent major sources of common variance, or should produce a reconstituted correlation matrix that approximates the original correlation matrix. Where there are several factors, a general modernity syndrome (and the concomitant predominance of statistical unidimensionality) can be established when the first factor captures items from most of the variable subsets and monopolizes common variance.

One of the primary objectives of factor analytic techniques concerns the identification and measurement of properties or traits which, due to their abstractness or complexity, are not directly observable. By virtue of this fact a fair to large number of surface variables are needed to explicate fully and isolate such a trait or traits. Thus, a useful factor solution (1) provides a pattern matrix with conceptually interpretable constellations of variables, and (2) extracts the major sources of common variance in a correlation matrix.

A central problem until recently has been the lack of statistical estimation of the second issue. As a result, a number of judgmental procedures, such as the screen test, have been used to estimate dimensionality. The trouble with such procedures is that inexperience and subjective bias can affect their use. Consequently, under- and overfactoring have been commonly encountered in exploratory studies. In the first instance, the interpretability of a factor matrix can change as one extracts additional factors. In overfactoring, random noise is introduced into the pattern matrix and can produce factors which are epiphenomena of chance variation.

This problem has been greatly minimized with the recent development of several statistical tests of dimensionality. Two deserve attention. The first is given by the goodness-of-fit test in maximum-likelihood factor analysis (Jöreskog, 1967; Jöreskog and Lawley, 1968). The second is provided by the parallel analysis criterion which has been transformed into a practical research tool by Montanelli and Humphreys, 1976 (see, also, Horn, 1965; Linn, 1968; Humphreys and Ilgen, 1969; Humphreys and Montanelli, 1975).

Maximum-likelihood factor analysis determines goodness-of-fit by examining the residual covariance matrix remaining after a factor solution. An acceptable goodness-of-fit (e.g., $p > .01$) is established when the residual eigenvalues approach equality (Gorsuch, 1974:139–41; Mulaik, 1972:161–7). This indicates that the factor solution approximates the patterns of covariation estimated to exist in a population covariance matrix.

A difficulty with this test, however, is that it is sensitive to differences in sample size.[5] As a result, the likelihood ratio can underestimate dimensionality in small samples and, conversely, overestimate in large samples (Browne, 1968; Burt, 1973; Harris and Harris, 1971; Montanelli, 1974; Humphreys and Montanelli, 1975). In such situations, the likelihood ratio should be used in conjunction with a Tucker reliability coefficient (Tucker and Lewis, 1973) which compensates for the effects of sample size.

The parallel analysis criterion represents a somewhat more reliable and considerably less expensive technique. It is, therefore, well suited to exploratory research. Here we proceed by inserting squared multiple correlations in the diagonal of the correlation matrix and factoring by means of the principal axes method. The process is then repeated on a second correlation matrix which is constituted from normally distributed random numbers, where the order of the actual and random data matrices is the same. The latent roots obtained from the actual and random data are then compared. The number of factors required to extract the sources of common variance is given at the point where the actual eigenvalue equals or drops below the random eigenvalue.

This technique has been rendered usable through the development of regression equations for predicting random eigenvalues (Montanelli and Humphreys, 1976). The estimated eigenvalues are virtually identical to those derived from monte carlo experiments. Thus, practitioners are spared the task of constructing random correlation matrices.

If the fit between data and the common factor model is adequate, this technique will yield a reliable estimate of factorial dimensionality. On the other hand, if the correlation matrix is ill-conditioned, it is possible to overestimate common factors.

---

[5] In addition, the most useful application of the maximum-likelihood estimation procedure is in confirmatory or hypothesis-testing factor designs. These models, however, presuppose a structural theory for the target domain in such a way that the parameters of the hypothesized model can be specified (e.g., Burt, 1973; Jöreskog, 1974; Mukherjee, 1973; Mulaik, 1975). Without such a theory, the use of confirmatory factor or structural covariance analysis is likely to be governed by ad hoc and post hoc considerations.

For the present study, in any case, the maximum-likelihood goodness-of-fit procedure yields dimensionality estimates which are either identical or very close to results derived from the parallel analysis criterion. The results are as follows:

Nation	*No. Factors*	χ^2	*Probability*	*Tucker Reliability*
Ghana	6	1,252	.05	.89
India	7	1,348	.00	.83
Brazil	5	1,293	.07	.90
Japan	7	1,218	.02	.88
USA	7	1,236	.01	.90

Similarly, if extant and theoretically important traits are overlooked in the battery, then dimensionality can be underestimated. As such, this technique cannot be used blindly, particularly in exploratory research ventures.

A Five Nation Analysis of Dimensionality

We can demonstrate dimensionality estimation by examining the dimensional properties of the Peshkin battery used in the Karsh study. The data were derived from field interviews administered to groups of farmers and industrial workers in Ghana, India, Brazil, Japan, and the United States.

The dimensionality established by the parallel analysis criterion is given in Table 4. As can be seen, four to five factors must be extracted from each sample correlation matrix to represent at least one-half of the common variance. Additionally, the proportion of variance across descending factors is such that at least two major factors appear in each matrix with the possible exception of India. Since a number of value themes, such as universalism/particularism, do not receive adequate representation in the present battery, it is likely that the reanalysis of other studies will isolate other value orientations with comparative significance. In sum, the factorial dimensionality and the structure of variance in the present study rule out unidimensional modernity constructs.

Table 4 also points to a problem. The required dimensionality calls for a rather large number of factors for both the Indian and Japanese samples. As mentioned, the accuracy of this criterion test depends on a reasonable fit between the common factor model and a set of data. As data depart from the model the criterion test will overestimate dimensionality.

Departures from the common factor model characterize the data for India and Japan. Closer inspection reveals that the communality estimates for the correlation matrices of these samples are below desirable levels. The mean communality estimates for the nation samples are as follows:

Table 4. Parallel Analysis Criterion Test: Factorial Dimensionality Estimation for Five Nations

	Nation Percent Common Variance—Actual Eigenvalue—Random														
Factor	Ghana			India			Brazil			Japan			United States		
Number	% Var.	Actual	Random	% Var.	Actual	Random	% Var.	Actual	Random	% Var.	Actual	Random	% Var.	Actual	Random

10					.81	.81				4.1	.93	.91			
11											.84	.89			

Ghana	.52
India	.40
Brazil	.52
Japan	.41
United States	.56

In factor analytic practice, an average communality estimate of below .50 is taken as a sign of departure from one of the assumptions of the common factor model. This means that a fair number of items do not share much common variance with other battery items. In other words, intercorrelations among items tend to run consistently on the low side.

Such an outcome can stem from a number of difficulties: (1) The items in the battery may not be tapping existing latent traits, hence, a problem of either construct or content validity. (2) The underlying distribution of data may depart substantially from the assumptions of linearity or multinormality. Like all regression models, factor analysis tends to be robust. But large departures from assumptions can lead to the sort of problems encountered here. (3) A sample may not possess sources of common variance. The individuals studied may share little in common or too much in common. The first situation will result in low intercorrelations, that is, data lacking an internal structure. The second may result in a distribution which is not multinormal or linear, or data with little variation.

In the present study, the following possibilities are likely: In India the research design forced us across several different cultural areas. I suspect that the problem here is due to low intercorrelations which reflect the cultural diversity of this sample. Japan, on the other hand, may represent the opposite situation. The Japanese sample has proved to be homogeneous in the extreme with regard to quantitative differences among the value patterns found (Rau, 1979:230–55). In the case of Japan, it is possible that the data distribution may depart meaningfully from the assumptions of normality or linearity. It is also possible that the attitudinal statements may not adequately tap Japanese values.

The major point is to underscore once again the early developmental stage of comparative value analysis. I have also shown how factor analysis can help to uncover major problem areas in value studies, problems which are not exposed by present statistical techniques. Moreover, factor analysis can help investigate content and construct validity, and can assist in the development of a structural theory of modernity.

This much, however, is certain. The present results indicate consistently a need to develop indices for value themes which depict independent sources of variation. The major problem is to define the central value traits contained within modern value systems. Such an undertaking will ultimately lead to scales with acceptable levels of content and construct validity.

Table 5 presents a preliminary approach to this problem. Here, we begin the conceptual interpretation of factor matrices through overview of the subscale representation on various factors. By itself, this shorthand method of substantive factor interpretation can obscure meaningful differences in factors with items from similar conceptual classes. The content variety among modernity subscales is sufficiently great that this constitutes a hazardous procedure. For example, the content of a number of the Peshkin achievement and universalism items concerns sex role stereotyping. Other status ascription items focus on locality, age, education, and so forth. If the gender items load together, one can view this as a women's emancipation factor, or, depending on the other items on the factor, a universalistic value syndrome. Such situations require a content or profile analysis of items on the factor. The present level of analysis is but a prelude to a detailed interpretation of factors in a companion paper (Rau, 1979:169–201).

With this in mind, one can observe a number of obvious patterns in Table 5. One demonstrative pattern is seen on the first factor in the Brazilian sample. This factor possesses the characteristics of a general modernity syndrome with a substantial number of items from nearly all the value subscales in the Peshkin battery. In relation to the salience of subscales in the other factor matrices, only the need-

Table 5. Percentage Subscale Items in the Peshkin Modernity Battery with Loadings of .30 for the First and Second Factors across the Five Nations*

	First Factor					Second Factor				
Subscale (N)	Ghana	India	Brazil	Japan	USA	Ghana	India	Brazil	Japan	USA
Universalism/ Particularism (8)	38	38	63	13	50	38	00	00	00	13
Ascription/ Achievement (8)	38	00	50	63	50	25	25	00	00	25
n-Achievement (12)	42	50	17	50	75	17	08	08	00	17
Closed/Open (5)	40	20	60	20	60	20	20	20	20	00
Dependent/ Independent (4)	00	00	25	25	75	50	25	00	00	00
Alienation/ Trust (4)	00	00	25	50	00	00	00	25	25	00
Religiosity/ Secularism (8)	50	00	63	13	00	00	63	38	38	100
Localite/ Cosmopolite (6)	50	25	17	00	17	00	00	33	00	50

* These results are derived from the Varimax, Principal Axes solutions used in Table 6.4. For reasons cited in the text, I have departed from the parallel analysis criterion for India and Japan. Hence, the present analysis is based on the extraction of five factors for Brazil and the United States, six factors for Ghana and Japan, and seven factors for India. The sixth factor, rather than the second, is listed for Japan since this is where the secularism items appear.

achievement subscale is underrepresented. It is possible that the meager representation of need-achievement in this sample may be an indirect function of this nation's religious tradition. The patterns in this factor matrix suggest that a modern Brazilian is also likely to be secular. Nonetheless, the fatalistic propensity of South American Catholicism may place a shadowy stamp on modern values through a suppression of a stress on achievement. Clearly, this is a speculative interpretation of the relation of religion and modernity in Brazil. I offer it as an example of the pressing need to consider more carefully both the nature and relationship among values and belief, and as one more indication of the desirability of measuring national manifestations of the great religious traditions.

The United States sample represents another pattern. Here, need-achievement and other activism items are strongly represented on the first factor. This factor could be labeled a general activism factor. In addition, the secularism items cluster on the second factor. The separation of the activism and secularism domains in the United States suggests either a compatibility or neutrality between religion and modernity in this sample. Note also the broad affinity between the first Brazilian and American factors with the important exceptions that the latter is completely asecular and has a heavy emphasis on achievement items.

The first Japanese factor is also asecular. In relation to Brazil and the United States, there is a conspicuous paucity of measures of value universalism. In addition, the Japanese factor reveals a rather balanced stress on both with the evaluative and affective elements of an activist value orientation which further distinguishes it from Brazil.

Finally, the Ghanaian sample may constitute a special case. First, a number of negative loadings are not represented in Table 5. This suggests that modernity in Ghana is syncretic and that Ghanaians may blend both traditional and modern value elements into an appositional value system (Jahoda, 1970; Le Vine, 1973). Does this typify Ghana's culture and level of development, or a general solution to the problem of modernity in some developing countries? Further research and analysis should focus on this issue. Also, the major distinction between the first and second factors in Ghana consists in the absence of secularism and cosmopolite items on the second factor. Otherwise, the two factors seem to represent differing combinations of general modernity themes.

On the basis of the subscale composition of factors, the overall patterns are as follows: First, secularism items factor separately from activism items in the United States, Japan, and India. Thus, the general practice of including both types of items in modernity scales is highly suspect. It also accentuates a concern in the debate under discussion. Comparative scholars must devote more attention to the content and construct validity of value scales, and need to more carefully delineate the nature, consistency, and number of modern and traditional value domains. Second, the composition of subscales on the first factor varies across the five samples. As such, the extent of cross-cultural equivalence among factor matrices is an open question, as is the larger question regarding the pancultural features of modern value systems. Due to the general nature of the present analysis nothing conclusive will be stated here. The question of pancultural value themes is addressed elsewhere (Rau, 1979:169–201) by means of statistical comparison of factors, and a content and conceptual interpretation of items on correlated factors. The present analysis, however, should reveal the nature of the problem.

CONCLUSION

This paper's objective is to raise questions that lack systematic discussion in literature on modernity scales. It represents a continuation of the debate of Armer-Schnaiberg, 1977 and Cohen-Till, 1977. Their investigations examine the concept of value modernity and measures associated with the concept. The basic question is whether overall modernity scales constitute valid constructs. Armer and Schnaiberg reject measures of the concept while Cohen and Till suggest that valid modernity constructs can be developed if the concept itself is more carefully and precisely specified.

The present report supports the major observations of both pairs of authors. First, this analysis suggests that the concept of overall modernity be rejected. While it is possible that overall modernity may be supportable in some cultural settings, the results from this five nation study indicate that the value themes subsumed within this umbrella concept should be represented as differentiable components of multidimensional value systems.

Second, the possibility of valid measures of modern and traditional values is still maintained. A central theme here is that the development of valid measures will require a multidimensional approach. A corollary theme is that many of the difficulties encountered in the comparative study of values stem from the unverified assumption of the unidimensionality of overall modernity and measures of this concept. The balance of this paper substantiates this viewpoint by examining how this assumption structures and circumscribes studies in the area, and by suggesting a new direction to working through problems in comparative value analysis. Hopefully, this discussion will provide an impetus for rethinking current research strategies, suggest more fruitful approaches to statistical analysis, and open discussion of an agenda for attacking mutual problems.

THE TRANSITION TO ADULTHOOD AS A CAREER CONTINGENCY*

DENNIS P. HOGAN
The University of Chicago

American Sociological Review 1980, Vol. 45 (April):261–276

Individuals in American society tend to agree that it is normatively appropriate behavior to order the events marking the transition to adulthood so that formal schooling is completed first, and so that both school completion and beginning of first job occur prior to marriage. This paper reports on the testing of the hypothesis that men who order their transition events in a nonnormative fashion experience reduced occupational status and earnings returns in their later careers. The study is based on the responses of 18,370 ever-married white males aged 20 to 65, who were employed in the experienced civilian labor force, and were interviewed in the 1973 Occupational Changes in a Generation II survey. While no difference in occupational attainments are observed, men who experience a disorderly transition to adulthood also experience lower earnings returns to their education, as well as substantial deficits in their total earnings.

INTRODUCTION

Prior to World War II, American males enjoyed considerable latitude in the ages at which they could choose to complete school, begin working, and first marry. This latitude is evidenced in the fairly wide dispersion in the ages at which men experienced these transition events. Beginning during the 1940s, and especially during the postwar period, the typical age at which males made these transitions became more concentrated on a few modal ages within a relatively narrow age range. Both average age at school completion and age at the beginning of first full-time job after the completion of schooling increased moderately due to increases in average years of school completed. Age at first marriage declined precipitously during the early postwar period (Winsborough, 1978; Modell et al., 1976; 1978).

The age patterns of these events indicate the "social times" in the life course of individuals during which the events typically occur.

> The notion of social time is based on the meanings of age, and refers to the ordering of events and social roles by age-linked expectations, sanctions, and options. The variable meanings of age represent social constructions which take the form of age norms and sanctions, [and] social timetables for the occurrence and arrangements of events. . . . (Elder, 1978:25–6).

What evidence is available indicates that individuals in American society express broad agreement regarding the appropriate ages for various transition events, and that this normative concept extends to specify not only the ideal age for each event, but also suitable age ranges—outside of which an individual is either "early" or "late" for the transition in question (Neugarten et al., 1965; Elder, 1974; Modell, 1979). The post-war changes in transition behavior imply that the old, accepted norms regarding the appropriate social times for these transition events may themselves have changed. Historical changes in normative beliefs about timing schedules are difficult to document, but what research has been done suggests that changes have occurred (see, for example, Modell [1979], for evidence about postwar changes in age-at-marriage norms.

An earlier version of this paper was presented at the annual meeting of the Rural Sociological Society in Burlington, Vermont, August 23–26, 1979. This research was supported by a Spencer Research Grant from the Division of Social Sciences, The University of Chicago; and by the Population Research Center. Computational work was capably carried out by Michele Pazul, and the paper was typed by Faye Gilbert and Susan Sherry. I thank Clifford Clogg, Glen Elder, David Featherman, and Rachel Rosenfeld for their comments. Any opinions, findings, conclusions, or recommendations are those of the author and do not necessarily reflect the views of any agency supporting this work.

The normative schedules regarding transition events not only specify the appropriate age for each event, but also prescribe an appropriate sequence of those events (Elder, 1974; 1978). For example, it is normatively preferred to delay marriage until schooling is completed and the couple can be self-supporting (Modell, 1979; Neugarten et al., 1965). The passage to adulthood is achieved in a socially prescribed way when a man first finishes his formal schooling, next becomes financially independent through employment at a full-time job, and finally forms his own family of procreation through marriage.

The actual timing of first marriage among American men is closely associated with age at school completion, with men showing a pronounced tendency to delay marriage until after the completion of schooling (Hogan, 1978a; 1978b; Winsborough, 1978). The timing of the early life-cycle events through which American boys pass in their transition to adulthood appears to be governed by an underlying tendency to order those events in a normatively preferred order (Hogan, 1978b). Men, therefore, can be characterized by their degrees of conformity to this hypothesized normative-ordering pattern (Hogan, 1978b).

As typical ages for school completion, first job, and first marriage have become more concentrated within narrow bands of modal ages, and, as the average age for each event has become more similar, the period of overall transition time to adulthood has narrowed, resulting in a more concentrated pattern of status changes (Elder, 1978; Winsborough, 1978; Modell et al., 1976). It has consequently become increasingly difficult for men to achieve the events marking the transition to adulthood in a normatively prescribed order (Hogan, 1978b).

Indeed, the ability of men to order their life-course events in a normative fashion varies by the unique history of the birth cohort into which they are born and, in particular, by the military service and educational experiences characteristic of their cohort. In general, time-consuming activities during the period of early adulthood—such as the achievement of advanced levels of education (undergraduate and/or graduate and professional training), or service in the military—result in postponements or preponements of school completion, first job, or first marriage that are disruptive of the usual sequence of life-cycle transitions (Hogan, 1978b; Mason, 1970).

Military service and higher education are particularly disruptive of the typical sequence of events among men born during the 1920s. Such men carried the heaviest burden of manpower supply during World War II and, thus, had little discretion in the timing of their military service. As a consequence, many more of these men married prior to the completion of schooling and/or beginning of work than did men born into different times (Hogan, 1978b).

Such a disorderly sequence of life-cycle events may be viewed as disrupting the harmony which usually exists between a man's own life style and the institutional structure that provides the social context in which he lives. It has been hypothesized that the consequences of such disharmonies with his social environment may persist over a man's life course (Elder, 1978; Hogan, 1978b). Previous research has demonstrated that men who deviate from the normative ordering of events experience higher rates of marital instability than men who make the transition to adulthood in a normative fashion (Hogan, 1978b). This paper (by examining the consequences of ordering pattern for occupational and earnings attainments in the later career) reports additional tests of the hypothesis that the variable order of events in the life course is an important life-cycle contingency.

Previous studies of the effects of the timing of life-cycle transition events on occupational status and earnings attainments have considered the timing of each event separately. Thus, age at school completion is usually divided into its component parts (age at beginning of school, level of educational attainment, years of educational disruption, and years of age-grade retardation or acceleration), and the consequences of these component parts are then examined. For example, Featherman and Carter (1976) report that among a cohort of men born between July 1, 1939, and June 30, 1940, those men who delayed postsecondary education after leaving high school, or who interrupted their posthigh school education, ultimately attained fewer years of education, even after controls for socioeconomic background, ability, and aspirations. Furthermore, men who were age-grade retarded in high school earned an average $2,400 less annually (when interviewed in 1972) than did men with similar background characteristics who did not experience such retardation.

It has proven difficult to disentangle the socioeconomic consequences of age at first job from the consequences of age at school completion because of their intricate interconnections (Duncan et al., 1972; Ornstein, 1976). Men who begin their first jobs relatively early have less advantageous family backgrounds and tend to remain at their first jobs for somewhat longer periods of time (Duncan, 1968; Ornstein, 1976). The "early" job takers achieve slightly lower levels of occupational attainments (2 to 3 points on the Duncan scale) compared with "late" job takers at similar levels of education. In part, however, this negative relationship of age at first job to occupational attainments may result from the earlier age at first marriage which is characteristic of early job takers (Duncan et al., 1972).

An early age at first marriage has a negative relationship to economic position in the early years of the life cycle, as does a very short interval between marriage and birth of the first child (Duncan et al., 1972; Coombs and Freedman, 1970; Coombs et al., 1970; Freedman and Coombs, 1966). A substantial component of this negative association is explained by the poorer family backgrounds and lower educational attainments which are characteristic of men who marry early or have short first-birth intervals (Duncan et al., 1972; Coombs and Freedman, 1970; Coombs et al., 1970).

We thus have evidence from a number of studies showing that the ages—at which a man finishes school, begins work at a full-time civilian job, and first marries—all act as life-cycle contingencies affecting his career occupational and earnings attainments. My objective in this paper is to demonstrate that the ordering in which these life-cycle transitions occur constitutes a career contingency of some importance in the life course. This effect of the temporal ordering of events is hypothesized to occur net of the effects of the age of occurrence of each of the component events.

Data

The data source for this study of the occupational status and earnings consequences of the temporal ordering of schooling, first job, and marriage is the 1973 Occupational Changes in a Generation II survey which was carried out in conjunction with the March demographic supplement to the Current Population Survey. In 1973, the eight-page OCG questionnaire was mailed out six months after the Marsh CPS and followed by mail, telephone, and personal call-backs. The respondents, comprising 88% of the target sample, included more than 33,500 men aged 20 to 65 in the civilian noninstitutional population. Also, blacks and persons of Spanish origin were sampled at about twice the rate of whites, and almost half the black men were interviewed personally. A complete description of the survey is found in Featherman and Hauser (1978).

In this paper, I am interested in the occupational attainments of men in the postschooling, economically active years, so the analysis is limited to men aged 25 to 65 in the experienced civilian labor force. Black men have lower occupational and earnings attainments than white men with similar background characteristics (Featherman and Hauser, 1978; Blau and Duncan, 1967), and black men less often make the transition to adulthood in a normative fashion compared with white men at similar levels of schooling (Hogan, 1978b). In order to estimate the pure effects of ordering pattern on career attainments—without contaminating the estimates by the effects of race—the analysis in this paper is restricted to white men. Finally, so as to remove the effects of nonmarriage on career attainments, the analysis is limited to men who have been married. These restrictions produce a population of analysis that includes ever-married white men aged 25 to 65 who are in the experienced civilian labor force.

Temporal Ordering Scale

The scale of temporal ordering used here was developed in Hogan (1978b). The scale is designed to measure the variation in the normativeness of the ordering pattern of transition events. The scale is based on the idea that the three events marking the passage to adulthood occur in a normative order only when a man first completes school, next starts to work, and lastly marries. A single inversion from this normative rank order occurs when a man either begins a job prior to finishing school, or marries prior to beginning work but after the completion of schooling. An extreme nonnormative ordering pattern occurs whenever a man marries prior to the completion of his education; this produces at least two inversions in the normative order.

All OCG respondents answered questions about the dates (month and year) in which they completed school, began their first full-time civilian job, and first married. In order to be classifiable on this three-category temporal ordering scale, a respondent had to provide information on at least the year during which he had completed each event.[1] These dates were used to classify the respondents into the three ordering categories. In cases where two events occurred during the same month, the ordering category closest to the normative pattern was assigned.[2]

Levels of Socioeconomic Background and Attainments

Men who completed the transition to adulthood in a normative fashion were from poorer socioeconomic backgrounds (i.e., their fathers' occupational status, fathers' education, and family income at age 16 were all lower than average; and they had a larger number of siblings) than did men who made the transition in a nonnormative fashion (Table 1).[3] While men

---

[1] In cases where the year of an event was given by the respondent but no month was indicated, a midyear (July) month of occurrence was assumed.

[2] These restrictions on the population of analysis result in the following number of sample cases representing men with each ordering pattern: 11,288 for the normative order, 3,379 for the intermediate nonnormative order, and 3,703 for men with the extreme nonnormative order. In carrying out statistical calculations for this paper, these sample cases were adjusted by a design factor of 0.75 to reflect departures from a simple random sample (see Featherman and Hauser, 1978: Appendix B). The adjusted number of sample cases is shown in Table 2. In estimating the structural equation models for this paper, a list-wise deletion procedure was followed for cases with missing data on one or more variables in the models. The number of sample cases on which the standard errors for the structural equation coefficients are based is shown in Table 1. A comparison of the characteristics of the men included in the structural equation models of this paper with the characteristics of all white men in the OCG-II survey showed that the procedures used in this paper produced no biases greater than 5% in mean of father's occupational status, proportion farm background, father's education, respondent's education, and respondent's occupational status. I therefore conclude that the sample on which this analysis is based —despite sample attrition due to missing data—is representative of ever-married white men aged 25 to 65 who were in the experienced civilian labor force.

[3] Paternal education is scaled in years completed according to the following recode of class intervals: no school, 0.0 years; elementary (1–4), 3.3 years; elementary (5–7), 6.3 years; elementary (8), 8.0 years; high school (1–3), 9.9 years; high school (4), 12.0 years; college (1–3), 13.8 years; college (4), 16.0 years; college (5 or more), 18.0 years. Number of high school (1–3), 9.9 years; high school (4), siblings is the number of brothers and sisters (not counting respondent). Farm origin is a dummy variable, with a score of 1 indicating that respondent's father was a farmer, farm manager, farm laborer, or farm foreman. Broken family is a dummy variable, with 1 indicating that the respondent was not living with both parents most of the time up to age 16. Family income at age 16 is based on the respondent's report of his family income when he was age 16, inflated to 1972 dollars using the Consumer Price Index. To allow for the differential occupational returns and earnings returns to an additional year of schooling at the grade school and high school level compared to the returns to an additional year of college, respondent's education is scaled as a spline function, following the procedures of Featherman and Hauser (1978). Persons with 0–12 completed years of graded schooling reported to the Current Population Survey are so indicated on the graded schooling variable; men with one or more years of college completed are scored 12 on the graded schooling variable. The college variable is scored 0 for those with no college, as 1 to 4 for those with 1 to 4 years of college, respectively, and as 5 for those with 5 or more years of college completed. Father's and respondent's occupation are scored according to Duncan's socioeco-

Table 1. Means and Standard Deviations of Background and Attainment Variables by Ordering Group

Variable	Normative		Intermediate Nonnormative		Extreme Nonnormative	
	Mean	Standard Deviation	Mean	Standard Deviation	Mean	Standard Deviation
Father's occupation	28.17	21.35	30.31	22.44	38.99	24.89

in the intermediate nonnormative ordering group are generally intermediate in their family background characteristics, they tend, otherwise, to more closely resemble the normative group than the extreme nonnormative group.

Men with extreme nonnormative orders are characterized by better early attainments as compared with other men. They thus enjoy an average of one more year of graded schooling and 2.3 more years of college than had men with normative orders. The intermediate ordering group is also intermediate with respect to educational attainment, but more closely resembles the normative group. Men with nonnormative orders are more likely to have spent some time in the military service. (These characteristics are in line with the findings reported in Hogan, 1978b; 1976).

Men with extreme nonnormative orders married at an average age of 22.5 which is 1.6 years younger than the average marriage age of men with normative orders. In line with their higher educational attainments, the men with nonnormative or-

---

nomic index for occupations (Duncan, 1961), since occupational socioeconomic status is the major dimension along which occupational positions persist from generation to generation (Hauser and Featherman, 1977). "Father's" occupation refers, as well, to the mother or other household head where the father was absent. Number of weeks worked by the respondent during the previous year is scaled in weeks according to the following recode of class intervals: None, 0.0 weeks; 1–13, 7.0 weeks; 14–26, 20.0 weeks; 27–39, 33.0 weeks; 40–47, 43.5 weeks; 48–49, 48.5 weeks; 50–52, 52.0 weeks. Earnings are expressed in 1972 dollars. Age at completion of schooling, age at first job, and age at first marriage are scored in single years of age. Birth cohort is represented by a series of dummy variables in order to control for differences in the birth cohort compositions of the ordering groups. A variable for years of work experience is not included since it would be highly collinear with the combination of the birth cohort and age at first job variables.

dering patterns remained in school until a later age than the men with normative orders. In fact, men with extreme nonnormative orders, even though they averaged only 3.36 more years of schooling (graded schooling and college), finished school 11.4 years later than men who had normative orders. The extreme nonnormative men also began working at the first full-time civilian jobs they held after completing their highest grade of school an average of 3.0 years before completing school.[4] This contrasts with other men who began working at full-time civilian jobs an average of 1.3 years after completing school.

The later age at first job together with the higher level of schooling of men in the nonnormative ordering category suggest that the first jobs of these men represent, actually, the beginning of their careers rather than merely the start of more tenuous "first jobs." This supposition is confirmed by the average first-job status of 57.4 points reported by the extreme nonnormative men, compared with average first job statuses of 29.4 for men with normative orders and of 33.4 for men with an intermediate ordering pattern.

It is not surprising, given their better socioeconomic backgrounds and above average early attainments, that men with extreme nonnormative ordering patterns report higher-status occupations and higher earnings as of 1973, compared to men with intermediate nonnormative and normative orders. Thus, the current occupational statuses of the men who marry prior to completing school are an average 21 points higher than those of men with normative orders, and their annual earnings are about $3,000 higher.

These simple comparisons run strongly counter to the hypothesis that nonconformity with normative ordering patterns in the transition to adulthood will reduce later career attainments. The remainder of this paper reports more detailed analyses which demonstrate that this apparent advantage of men with nonnormative orders disappears when their more favorable social backgrounds and early attainments are taken into account. While the results do not confirm the hypothesis for occupational attainments, they provide strong confirmation for the hypothesis in regard to earnings attainments. The paper concludes with a discussion of various factors that may be producing these results.

The Process of Occupational Attainment

The analysis of occupational attainment processes traditionally focuses on either intergenerational occupational mobility models or on structural equation models which show occupational status attainments as a function of family background and education (Blau and Duncan, 1967; Featherman and Hauser, 1978). In order to test fully for differences among the three groups in the process of occupational attainments, I carried out both types of analyses.

A comparison of the intergenerational occupational mobility processes of the three ordering groups indicates that the minimum degree occupational mobility between fathers and sons is 41% among men with extreme nonnormative orders, but only 24% among men with other ordering patterns.[5] Most of this difference is accounted for by the very pronounced recruitment, into the salaried professions, of men who have extreme nonnormative orders. Among such men, 27.4% more are in the salaried occupations (compared to their fathers), while the shift is only 6.6% among men with intermediate orders and only 4.7% among men with normative orders. Despite these differences in minimum mobility, rates of expected and observed mobility are virtually identical.

In order to control for the effects of structural mobility, a proportional adjustment procedure was carried out, which adjusted the margins of each matrix to those of the normative ordering group (see Hauser and Featherman, 1977).

---

[4] This is the definition of first job in the OCG-II survey. An alternative definition of first job would perhaps have been preferable for this analysis, but the bias resulting from the OCG-II definition is probably slight. See Hogan (1978b; 1976) for a complete discussion of the first job variable.

[5] A 17-category major occupation group classification is used. The occupational classification is the same as that used by Blau and Duncan, 1967, and Featherman and Hauser, 1978.

* Regression coefficients larger than twice their standard errors.

There are no significant differences in intergenerational mobility patterns among the three groups, once differences in origin and destination marginals are taken into account.

Turning to an examination of the occupational status achievement process among the groups, we find that the superior occupational status level of those men in the extreme nonnormative group is largely accounted for by their superior educations. Direct standardization for level of education results in an average current job status of 44.0 among men with normative orders, 43.4 for men with intermediate nonnormative orders, and 45.9 for men with extreme nonnormative orders.[6] These standardized figures may be compared with the unadjusted figures of 39.4, 41.7, and 60.2, respectively. While standardization for education does not reverse the pattern, it does attenuate the results in a direction consistent with the hypothesis.

Can controls for other background and early achievement variables reverse the occupational status differentials among the groups, in line with the hypothesis that degree of normativeness should be positively associated with occupational status? To answer this question, separate structural equation models of the occupational status attainment process were estimated for each ordering group (Table 2).These models incorporate all of the family background variables commonly used as independent variables (see Duncan et al., 1972). Educational attainment is scored as a spline function to allow for the differing occupational returns to a year of graded schooling and a year of college (see Featherman and Hauser, 1978, for a discussion of this specification). Veteran status and birth cohort are both included as control variables because both characteristics of an individual are known to be associated wth his ordering pattern, and are probably related to his occupational attainment (see Fligstein, 1976). Age at the completion of schooling, beginning of first job, and first marriage are included so that any differences observed among the ordering groups are due to the ordering of the component events, and not to the individual timing of one or more of those events.

---

[6] The education distribution for the entire population of analysis was used as the standard.

The sequence of transition events does not affect occupational status returns to family background, but it does have substantial consequences for the occupational returns to education, military service, and first job status.[7] As hypothesized, men with normative orders receive higher returns to a year of graded schooling than men who marry prior to completing schooling (2.31 occupational status points versus 1.08 points), and their occupational returns to years of college are also higher (4.46 versus 3.01). As anticipated, the occupational returns to a year of graded schooling and to a year of college are intermediate for the intermediate ordering group. A disorderly pattern of events marking the transition to adulthood thus reduces the returns a man gains for each additional year of schooling. Therefore, although advanced schooling is desirable for men as a way to increase their occupational achievements, the maximum occupational returns to schooling can be received only if their schooling is completed prior to both the beginning of their first full-time civilian job and their first marriage, controlling for other variables.

A disorderly pattern of events increases the occupational status returns to first job. This confirms that the first job is more important for men who begin that job relatively late in life, after considerable schooling, because it represents the beginning of a career trajectory. For men who begin their first job at a younger age, but after the completion of schooling, the first job status is not as closely tied to later occupational attainments because it may represent a more tenuous sort of labor force (and career) attachment.

Structural equation models omitting the first-job variable show a pattern of differential occupational returns to education in a much attenuated form. This indicates that part of the reason for the lower returns to an additional year of education among men with nonnormative ordering patterns is due to the greater importance of first job as an intervening variable among such men.

In order to decompose the source of the higher overall occupational status attainments of men with nonnormative ordering patterns into components due to differences in background and to differences in process, the means of the independent variables for each of the nonnormative ordering groups were inserted into the structural equation models estimated for men with normative orders, and predicted occupational attainments were calculated. A comparison of the predicted and actual scores permits an assessment of the penalty or advantage experienced by each of the nonnormative groups as a result of differences in the process of occupational attainment (Table 3).[8]

Most of the 2.06 occupational status-point advantage of men with intermediate nonnormative orders compared to men with normative orders is due to their better social origins (1.13) and higher educations (1.58). Men with intermediate nonnormative orders suffer a 0.88 status-point disadvantage in the process of attainment, compared to men with normative orders. That is, men with the same characteristics on the independent variables as these men would have occupational status scores an average of 0.88 points higher if they experienced transition events in a normative way.

Superior social origins account for 5.60 of the 21.05 status-point advantage of men with extreme nonnormative orders compared to those with normative orders, and their greater years of graded schooling and college account for an additional 14.64

---

[7] The structural equation models for the occupational attainment process differ significantly among the ordering groups ($F = 1.56$, with 41 and 11,274 degrees of freedom; $p < .02$).

[8] This type of multiple regression standardization procedure has been widely used (see Duncan, 1968; Althauser and Wigler, 1972: Hogan and Featherman, 1977).

points of their occupational status advantage. Net of the effects of social background and education, the better first jobs of men with extreme nonnormative orders adds 1.70 points to their average status scores. The overall penalty suffered for an extreme nonnormative ordering of events is a 0.60 point deficit in expected occupational status.

This analysis of the occupational attainment process does not confirm the hypothesis that a disorderly sequencing of events marking the transition to adulthood reduces expected levels of occupational attainment. While the net returns to a year of schooling are less among such men, this is mainly a function of the greater importance of first job as an intervening variable. Overall, the net deficit suffered as a result of a disorderly sequencing of events is less than one occupational status point. Therefore, the ordering of transition events leading to adulthood does not affect occupational attainments in the later career. The models also indicate that the age of occurrence of each of the events marking the transition to adulthood have only trivial effects on occupational attainments.

Table 3. Components of Differences between Occupational and Earnings Attainments of Intermediate and Extreme Nonnormative Ordering Groups and Men with Normative Ordering of Events*

	Ordering Group	
Attainment and Components	Intermediate Nonnormative	Extreme Nonnormative
Occupational Status:		
Social origins	1.13	5.60

Weeks worked	0	−65
Residual	−450	−1329
Total difference	84	3046

* The structural equations for men with a normative ordering pattern are used for the standardization.

The Process of Earnings Attainments

The next step in the research is to test the hypothesis that men with nonnormative ordering patterns suffer earnings deficits as a result of their distinctive ordering patterns. As already mentioned, the gross earnings differentials are patterned exactly opposite the hypothesized ordering, with men with extreme nonnormative orders earning $14,251 in 1972, compared to $11,550 for men with intermediate ordering patterns, and to $11,320 for men with a normative ordering pattern. But this is not surprising, given the better educations of men with deviant ordering patterns.

Comparing the earnings of men with different ordering patterns at each level of education, we find the expected differentials emerge among men who are high school graduates or better (Table 4). Among high school graduates, men with normative orders have average earnings $328 higher than men with extreme nonnormative orders. This differential increases with higher levels of education to $524 among men with one to three years of college, $988 among men with four years of college, and $5,124 among men with one or more years of graduate or professional schooling. The intermediate group has an intermediate earnings position only among men with one to three years of college or with graduate or professional training. Standardizing for education, the three ordering groups show the hypothesized pattern, with men with normative orders earning $12,407, men with intermediate nonnormative orders earning $12,018, and men with extreme nonnormative patterns earning $11,725.

The earnings advantage accruing to men with normative ordering patterns is concentrated among men who are in the professional and managerial occupations or are farmers, when standardized for educational differentials among the ordering

Table 4. Mean Earnings in 1972 by Educational Level for Ordering Group

	Ordering Group

[b] Directly standardized, using the education distribution for the total population as the standard population.

groups within each category of occupation (Table 5). This difference amounts to $1,258 among the professionals; $1,440 among the managers, officials, and proprietors; and $907 among the farmers. The men with intermediate ordering patterns have intermediate earnings patterns among professionals, and among managers, officials, and proprietors, but not among farmers. There appear to be no earnings differentials among the ordering groups for men in the lower white-collar and blue-collar occupations.

Structural equation models for the earnings attainment process can help explain the source of these differentials by indicating the total magnitude of the earnings deficit suffered by men with disorderly transitions to adulthood, and by showing what differences in process produce these earnings deficits. The earnings returns to an additional year of graded schooling and of college differ markedly by ordering pattern (Table 6).[9] Whereas men with normative orders earn $218 for each additional year of graded school and $911 for each additional year of college, men with intermediate nonnormative orders enjoy lesser returns of $140 and $786, respectively, and men with extreme nonnormative orders get a nonsignificant return to additional years of graded schooling, and only $414 for each additional year of college. A one-year delay in the completion of schooling or age at first job appears to depress the earnings of men with nonnormative orders, although the size of the loss remains small.

The better social origins of men with extreme nonnormative orderings account for $1,285 of their $3,046 earnings advantage over men with normative origins (Table 4). Their better educations provided them with an additional $3,123 in earnings. Their better first jobs and more favorable birth cohorts add about $250 (each) to their earnings advantage. But differences in the process of earnings attainments (between men with extreme nonnormative orders and those with normative orders) penalizes, by a total of $1,329, the men who marry prior to finishing school. As the detailed examination of the structural equations model indicated, this penalty is primarily due to their poorer earnings returns to graded schooling and college.

The men with intermediate nonnormative ordering patterns have gross earnings that are about equal to the earnings of men with normative orders. But this results from the counterbalancing effects of their better social origins and educations—which add $338 and $285, respectively, to

---

[9] The structural equation models for earnings attainment differ significantly among the groups ($F = 2.64$, with 45 and 11,265 degrees of freedom; $p < .01$).

Table 5. Mean Earnings in 1972 by Occupational Level For Ordering Groups

	Ordering Group

[a] Directly standardized, using the education distribution for the total population of the same occupation group as the standard population; the education variable was categorized into four categories—less than high school, high school, some college, and college graduate.

their average earnings—and of the earnings penalty of $450 suffered as a result of differences in process. As in the cases of the extreme nonnormative men, this penalty operates primarily via reduced earnings returns to graded schooling and college.[10]

Thus, the sequential ordering pattern of life-course transition events has an important impact on the earnings attainments of men in their later careers, but does not substantially affect occupational attainments (measured by occupation group or by occupational status score). The earnings penalty for having transition events out of their appropriate sequence amounts to $450 among men who marry after completing schooling, and to $1,329 among men who marry prior to completing their schooling.

This pattern of differential earnings returns to a year of schooling cannot be attributed to a differential rate of school disruptions among the out-of-order groups. Restricting the analysis to men with no interruptions in their schooling, the earnings differential between men with normative orders and those with intermediate nonnormative orders amounts to $285, and the earnings penalty for marrying prior to completing school is $1,243. The earnings differentials by ordering group are concentrated among men with one or more years of college who are professionals, managers, officials, or proprietors. Restricting the analysis to this

---

[10] The structural equation models reported used earnings rather than the natural log of earnings as the dependent variable. My substantive interest in this paper is on the actual process of earnings returns among the ordering groups, and not on determinants of relative earnings position (as would be provided by a semilogged structural equation model for earnings attainment). In any case, a regression analysis using log-earnings as the dependent variable produced the same pattern of differential returns to education for the ordering groups. The relative earnings returns to an additional year of graded schooling, controlling for all other independent variables, are .033 for men with normative orders, .018 for men with intermediate orders, and .026 for men with extreme nonnormative orders. The comparable relative earnings returns to an additional year of college are .041, .039, and .021 for the ordering groups, respectively. When the three ordering groups are included in a single equation, the differences in intercept are in the expected direction, with an intermediate nonnormative ordering pattern reducing relative earnings position by .030, and an extreme nonnormative order reducing relative earnings position by .063.

population, the structural equation models show a $514 earnings deficit for men with an intermediate ordering pattern and a $1,479 deficit for men who marry prior to completing school. These differentials persist when controls are introduced for five-year job-tenure cohorts.

These findings apply to men in both their early and later careers. Separate structural equation models were estimated for each of the ordering groups for men aged 26 to 39 and 40 to 65. There were no differences in occupational attainments, overall, at any age, although a pattern of reduced occupational status returns to each year of school, similar to that for the population aged 25 to 65, are observed. The expected pattern of earnings returns, by ordering group, is observed for all groups except the older men with intermediate nonnormative orders. Thus, among younger men, the earnings returns to an additional year of college are $754 for men with normative orders, $574 for men with intermediate orders, and $428 for men with extreme nonnormative orders. Among older men, the comparable earnings returns are $1,097, $1,070, and $458, respectively. The younger men with intermediate ordering patterns experience a total deficit of $185 and those with extreme nonnormative orders have earnings $874 lower than men with normative orders. Among older men, those with intermediate ordering patterns experience no overall earnings deficit, but men who marry prior to finishing school have earnings $1,558 less than would otherwise be expected.

Summary and Conclusions

Throughout the twentieth century, American society has become more distinctly age-graded, with certain chronological ages being recognized as appropriate for a variety of social roles. This historical tendency toward sharper age-grade distinctions has become especially pronounced since World War II. Whereas males making the transition from youth to adulthood in the prewar period faced a relatively loosely defined set of ages for the completion of schooling, the beginning of work, and marrying, a substantial narrowing of the variation in the usual age-range for each of these events occurred in the postwar period. Furthermore, the average age at school completion and at the beginning of first full-time civilian job following school increased somewhat in the postwar period, while the average age at first marriage declined substantially. As a result, it became increasingly difficult (for those young men making the transition to adulthood during the postwar years) to adhere to the normative timetable for each transition event while, simultaneously, maintaining the sequence of transition events that is normatively preferred. This is reflected in a higher proportion of men making the transition to adulthood in a nonnormative fashion during the postwar period.

It is especially difficult for men who attend college, graduate, or professional school to maintain a normative ordering of events, because an extended postponement of marriage until after the completion of schooling will make them "late" marriers, in relation to other members of their cohort. Such a postponement could, if strictly adhered to, even result in the loss of a desirable marriage partner who might decide to marry someone else rather than wait and, then, herself become "late" on the normal marriage schedule of her cohort. As a result of the joint effects of the norms regarding the desirability of a college education and marriage at the "right" age, some men marry prior to completing their schooling, thereby violating the normative proscription that schooling should be completed prior to marriage.

While this violation of the ordering norm may be preferable to dropping out of school (to the detriment of career socioeconomic attainments) or to postponing marriage until a later age than usual (and risking the loss of a suitable marriage partner), it does not occur with impunity. Men who marry prior to the completion of schooling receive much lower earnings returns to a year of graded school and a year of college than do men who adhere to the ordering norm. Overall, this deficit amounts to over $1,329 per year. The penalty is most substantial among men who are college graduates, especially those with one or more years of graduate or professional school. The earnings deficit is also most pronounced among men who are in the higher-status white-collar occupations. Men with intermediate nonnormative orders experience a somewhat smaller—but nonetheless substantial—earnings deficit of $450.

The analysis presented here indicates that a deviant ordering of transition events causes deficits in earnings, but not in occupational status attainments. Why are occupational attainments unaffected by the ordering of transition events? What is the mechanism that produces lower rates of earnings returns for men with deviant ordering patterns? There are a number of possible answers to these questions. While the data set used in this analysis is appropriate for testing the consequences of transition-event ordering patterns, it does not readily lend itself to the test of these alternative hypotheses. The hypotheses I mention will, therefore, be speculative; if they are found sufficiently compelling, they may provide a basis for future research.

The first possibility is that men who marry prior to the completion of school, and, to a lesser extent, men who marry before beginning their first job (but after completing school) may be less geographically mobile than single men, and this depresses their earnings. This hypothesis is based on two related ideas: (1) that men who are married are less geographically mobile than single men, and (2) that geographic mobility is an important mechanism by which men place themselves in more favorable job markets where higher wages are available (see Eldridge and Thomas, 1964; Blau and Duncan, 1967; Featherman and Hauser, 1978). The potential earnings gains from migration have historically been the greatest for highly trained men in the higher-status occupations (Featherman and Hauser, 1978), possibly accounting for the reason that earnings deficits are associated with deviant ordering patterns among only the better-educated, higher-status white-collar occupation men.

A second possibility is that men who are working and/or married while in school may spend less time on their academic studies than do men who are single while in college, graduate, or professional school. Such men possibly would obtain a smaller intellectual return from each additional year of schooling. Men with nonnormative transition orders therefore would have lower educational attainments (measured by achievement scores) than would men with normative transition orders who have the same number of years of schooling. To the extent that educational attainments promote on-the-job productivity, men with nonnormative orders would be less productive on the job. This might be reflected in lower wages, salaries, commissions, and profits accruing, overall, to such men. If employers hire men on the basis of years of schooling (or highest degree completed), they would not discriminate against married men in hiring them for their first jobs following school completion. In fact, they may prefer such men because of the presumption that they will prove to be more "stable" employees than single men. Also, at the higher-degree levels, many of these men will be self-employed and their ordering patterns would not affect their occupations. The lower productivity of the men with nonnormative orders would become apparent only after they begin work, and would then result only in lowered earnings (not in effect upon occupation choice). While this explanation is certainly plausible, it is complex, and will prove very difficult to test empirically.

Meanwhile, skeptics may wish to offer the alternative "beer-guzzler" hypothesis, which states that single students spend more time partying and less time doing "serious" studying than do students who are married and/or working.

A third possible explanation of the findings of this analysis is that men who marry prior to completing school and/or beginning work prefer to choose family achievements over career achievements. This type of choice, if made repeatedly over the life cycle, would ultimately depress career achievements below the level attained by men at similar levels of education who choose to emphasize career over family concerns. Bailyn (1976) and Bailyn and Schein (1976) have drawn attention to such an "accommodative" pattern in which the demands of work are subordinated to those of the family. Their study of 1,300 M.I.T. alumni suggests that such an accommodative pattern may act as a career detriment, particularly in technical and entrepreneurial occupations. While the accommodative solution of the conflict between family roles and work roles may depress achievements in a given occupation (in particular, earnings attainments), and may hinder upward occupational mobility beyond the career beginning, it may be insufficiently detrimental to cause downward career occupational mobility. In this way, ordering patterns of transition events would have a greater impact on earnings than on career attainments.

Regardless of which, if any, of these alternative explanations accounts, in the later career, for the earnings deficits that are associated with a disorderly sequencing of the transition events leading to adulthood, the research reported here has demonstrated the importance of a life-course perspective in understanding the family and career histories of American men. American men attempt to order the completion of schooling, beginning of first job, and first marriage in a normative fashion. At the same time, they attempt to adhere to normative constraints regarding the appropriate ages for each of these transition events. These normative constraints often conflict with the desire to enhance career chances through the achievement of higher levels of education. Those men who resolve this conflict by violating the norms regarding the appropriate ordering of transition events experience reduced earnings returns to additional years of graded schooling and college, and they suffer substantial earnings deficits during their later careers.

None of the alternative explanations I have offered for this finding suggests that it is the imposition of societal sanctions (resulting from the violation of the ordering norm per se) that has produced the earnings deficits of men violating those norms. Rather, they suggest that, in the educational and career achievement processes, there are structural factors that account for the earnings deficit associated with a nonnormative transition to adulthood. Thus, the scheduling of events (timing, spacing, and sequencing) by which American males make the transition from adolescence to adulthood has lasting consequences for career attainments in the later life course.

AN OPPORTUNITY LABOR DEMAND MODEL AND MARKOVIAN LABOR SUPPLY MODELS: COMPARATIVE TESTS IN AN ORGANIZATION*

SURESH L. KONDA
SHELBY STEWMAN
Carnegie-Mellon University

American Sociological Review 1980, Vol. 45 (April):276–301

In this paper we comparatively test three models of individual mobility in an organizational internal labor market. The data are on a police work force and its managerial staff. Two of the models are Markovian; the third, a vacancy model. In each model two types of decision-makers are postulated—managers selecting individuals for promotion and workers deciding to stay or leave. Individuals are distinguished by seniority within each grade. The vacancy or labor demand model's predictive capability was consistently better than either Markovian model—for long (10 years) or short (3–5 year) term forecasts.

1. INTRODUCTION

Internal Labor Markets

In the 1950s both sociologists and economists were discussing the fragmentation of the national work force into distinct (internal) labor markets (cf. Caplow, 1954; Kerr, 1954; Ross, 1958). Recently, this perspective, which is again gaining attention in both fields (Spilerman, 1977; Stewman, 1975a; 1975b; Stolzenberg, 1975a; 1975b; Doeringer and Piore, 1971), is rounding out the large omission of institutional processes within the more prevalent perspectives of status attainment in sociology (Blau and Duncan, 1967; Duncan et al., 1972; Jencks et. al., 1972; Hauser and Featherman, 1974) and human capital in economics (Mincer, 1974; Becker, 1975).

The most comprehensive theoretical treatment of internal labor markets (ILMs) is given by Doeringer and Piore (1971). Spilerman (1977) extends their treatment by tying careers to ILMs. The theory of internal labor markets postulates that many available opportunity sets within the national pool of jobs have restricted entry ports and internal rules regarding mobility and wages. Moreover, different ILM processes operate at different levels of analyses—organizations, industries and occupations—with varying degrees of openness to the external supply of labor. Specific empirical tests demonstrating the operation of internal labor market process have been conducted by Stolzenberg (1975a; 1975b) for occupational markets and by Stewman (1975a; 1975b) for an organizational market.

Individual Behavior and Job Opportunities

Since most theoretical and empirical work in both sociology and economics has not taken into account the structural effects of internal labor markets, we may raise the question of what governs individual movement within such systems. Two streams of analytical development seem relevant: (1) work on labor supply, generally involving Markovian models and (2) work on labor demand, incorporating job vacancies. Illustrative of the developments in labor supply are Tuma's (1976) semi-Markovian model, Wise's (1975) Markov chain model and Spilerman's (1977) development of the career-line construct. Both Tuma and Wise generate individual mobility parameters from a regression model of individual attributes,[1] which results in a nonstationary multivariate Markovian model of labor supply.[2] The significance of this work for the present paper lies in its attempt to further specify labor mobility beyond the simple Markov chain process. Prior significant work includes Blumen et al. (1955), Hodge (1966), McGinnis (1968), Henry et al. (1971), McFarland (1970), Spilerman (1972), Mayer (1972) and Sørenson (1975).

The second major development postulates that the nonstationarity of individual mobility arises from fluctuations in the demand side of the process. Organizational internal labor markets have been modeled from both supply and demand perspectives (see Forbes [1971] and Young and Vassiliou [1974], respectively), but from a theoretical point of view, demand models appear preferable unless some known labor supply mechanism, such as seniority, governs mobility. The foremost work on organizational demand processes is, of course, White's (1970) model of vacancy chains and Bartholomew's (1963; 1973) renewal models. Empirical tests to date strongly confirm the operation of chain reactions of vacancies in organizational job systems (White, 1970; Young and Vassiliou, 1974; Brown, 1975; Stewman, 1975a). Thus, there is strong evidence of the need for incorporating *both* labor supply and labor demand mechanisms when attempting to explain individual mobility in an organizational internal labor market.

Our purpose is to describe and comparatively test three models of individual mobility in an organization. Two of the models are Markovian; the third, a vacancy model. In each model two types of decision makers are postulated—managers selecting individuals and workers deciding to stay or leave. We know of only two other cases in which organizational labor models have been comparatively tested (Young and Vassiliou, 1974; Stewman, 1978), neither of which postulated decision processes or individual heterogeneity of work force. In short, we will make assumptions regarding individual behavior and, at least in the vacancy model, merge these assumptions with assumptions regarding the underlying structure of opportunities.

The data provide information on only one attribute—seniority in present grade—but this attribute is viewed as particularly important in affecting individual behavior in an organization. Exit rates, for example, may be expected to decline quite rapidly as seniority increases until the possibilities of retirement come into play (see Bartholomew, 1973; Young, 1965; 1971).[3] On the other hand, we know very little about how seniority interacts with hierarchical opportunity. McGinnis (1968) hypothesizes an inverted U-shaped curve for intraorganizational movement such as promotion. But, as yet, no one has empirically examined the form of these curves. Normative issues also arise when we consider relations between seniority and promotions. In a social psychological study of organizational managers in two firms, Sofer (1970) found explicit promotion expectations and "trauma" regarding stratum seniority and promotion. Certain norms were perceived about the maximum level of seniority beyond which the opportunity for promotion was negligible. In addition, Young (1971) has considered a promotion-exit linkage, which he called a "norm of fairness." He suggested that a certain level of promotion would become expected and when the organization's promotions dropped below this expected level, exit rates would increase. In subsequent analytical and empirical work, however, Young (1974) dropped this line of reasoning and pursued vacancy modeling per se. In this paper, we will consider a range of interactions between seniority and opportunity by postulating alternative models of individual mobility and by comparatively testing these models over time.

---

[1] Tuma utilized data on job attributes—occupation and industry—but since the attributes were of the individual's currently held job, not his job after the move, we may also consider current job held as an individual attribute. Whether or not there is a match between his resources and rewards in the occupied job is an important topic, but the issue remains within the sphere of labor supply. Tuma's inclusion of a variable "historical change" is an attempt to move beyond the supply orientation, however. Another semi-Markovian theorist, who focuses on geographical rather than labor mobility, is Ginsberg (1972). Furthermore, Ginsberg also treats destination attributes causally and is instructive in this regard.

[2] At the individual level Wise's model assumes stationary probabilities; however, at the aggregate level the process is nonstationary as a function of the heterogeneous distributions over time. Tuma's model, on the other hand, is also nonstationary at the individual level due to its incorporation of such variables as age and seniority.

[3] Both McFarland (1970) and Bartholomew (1973) have pointed out that decreased mobility rates may have at least two theoretical explanations: (1) population homogeneity with duration effects and (2) population heterogeneity such that persons with higher seniority also have lower loss rates (constant over time). Thus, the two conceptualizations differ in

Plan of the Paper

There are four main analytical sections to follow and a brief overview of each is provided at this point. In Section 2 we fully describe the three models and hence only a brief note on each is given here. The vacancy or demand model asserts that an individual's promotion chances over time are determined by the number of opportunities available, managerial preference by seniority (given that a vacancy is to be filled internally) and the sufficiency of labor at the desired seniority levels. The simplest Markovian model assumes a constant promotion probability at a seniority level; hence, the individual's promotion chances are determined by his seniority level and successive cohorts of individuals experience the same set of promotion probabilities. The alternative Markovian model postulates a stable organizational level process of internal flows rather than a stable individual-level process. That is, grade-level promotion probabilities are assumed to be a fixed proportion of the internal labor supply at each grade. Given this number of promotions, an individual's promotion chances are determined by managerial preference per seniority level and the sufficiency of labor at those desired levels.

In Section 3 we focus on estimates of the parameters of each model. Particular attention is given to each model's treatment of the managerial selection process and of the major differences in promotion probabilities across models; the differences in imagery of the promotion process are quite dramatic.

Section 4 presents the comparative tests of the three models over a ten-year period. The data are on a police work force and its managerial staff. One of the issues in these tests is whether seniority operates both to rank individuals within grade and to determine promotion rates or whether its effect is conditional on opportunities. A second and related issue is the specification of the underlying behavior of the process—managerial selection, exit decisions that are conditional on not being promoted, and chain reactions of vacancies across grades. We know there are distinct vacancy effects (cf. White, 1970), but, as yet, we do not know the significance of vacancy processes for individual movement. The comparative test of the demand model should begin to inform us about vacancy effects on individual behavior, as well as the interaction of vacancies with individual attributes.

Finally, in Section 5 we probe further into the relations between opportunities and individual behavior by using the demand model. The analysis also enables us to take a harder look at the underlying behavior of the process as depicted by the demand model. Inferential evidence of cohort effects and variable selection rules is found, and the implications of interdependent vacancies are shown.

---

their initial assumptions, each explaining declining mobility over time. Since our population attribute data are limited to seniority, we will treat only seniority effects here. For an attempt to separate duration and other population heterogeneity effects, see Heckman (1977).

2. ORGANIZATIONAL ILM MODELS

Opportunity Labor Demand (OLD) Model

The opportunity model is a variant of Bartholomew's (1973) renewal model (cf. Hopes, 1971 and U. K. Civil Service Department, 1974), with extensions to permit growth and allocation of new jobs per stratum, internal selection rules, and an exit decision that is conditional on promotion. The model is also consistent with White's (1970) vacancy chain model in that it includes chain reactions of vacancies. No explicit links between individual vacancies are considered, however, and therefore vacancy chains are not themselves units of analysis. In short, this model is less comprehensive in its portrayal of total vacancy behavior than White's model. The loss of this aspect of the structural representation is not viewed as significant here since our purpose is to predict movement of individuals across grade boundaries.

Divide the ILMs population into k grades. Let $n_i(s,t)$ denote the observed number of persons with seniority s in grade i at time t and $\bar{n}_i(s,t)$ the corresponding number *expected* or *derived* from the assumptions of the model.[4] Let the probability that an individual in grade i with seniority s at time t who moves to grade j in one discrete time period be $p_{ij}(s,t)$ and the associated probability of exit from grade i be $p_{io}(s,t)$. Aggregate grade sizes and probabilities are simply the proportion of seniority level s in grade i at time t.

For the simple case where (1) promotion is only to the immediately higher grade, (2) no jobs are abolished, (3) there is no lateral recruitment and (4) ILM size is constant, Bartholomew (1973) developed a discrete time, equilibrium equation for his renewal model as follows:

$$n_i(t) = \sum_s n_i(s,t) \tag{1}$$

$$p_{ij}(t) = \sum_s \alpha_i(s,t)\, p_{ij}(s,t), \tag{2}$$

and

$$p_{io}(t) = \sum_s \alpha_i(s,t)\, p_{io}(s,t) \tag{3}$$

where

$$\alpha_i(s,t) = \frac{n_i(s,t)}{n_i(t)}, \tag{4}$$

$$\bar{p}_{i,i+1}(t) = \frac{\sum_{j=i+1}^{k} \bar{n}_j(t)\, p_{jo}(t)}{\bar{n}_i(t)}. \tag{5}$$

The numerator is the *cumulative* number of persons exiting from all higher grades, thereby generating job vacancies, and the denominator is the number of persons in the origin grade or promotion pool. Given the exit rates and initial grade distribution, $\{n_i(0)\}$, the model derives the expected promotion probabilities. Note that $\bar{p}_{ii}(t) = 1 - [\bar{p}_{i,i+1}(t) + p_{io}(t)]$.

The above model takes on interesting dynamic properties once we introduce the following types of subprocesses:

(1) Growth—new jobs and their allocation per grade;

(2) Managerial Selection Rules—the decision to fill a vacancy internally or externally and the preference by seniority level if the choice is internal;

(3) Worker Exit Decisions—the decision by individual workers to stay or to leave the firm, conditional on not being promoted.

Growth. Growth is embedded in the model by taking into account new job vacancies as well as vacancies arising from individuals leaving the ILM. Moreover, we will also treat the exit probability (to be derived shortly) as a derived term. The equation becomes:

$$\bar{p}_{i,i+1}(t) = \frac{\sum_{\ell=i+1}^{k} \bar{n}_\ell(t)\, \bar{p}_{\ell o}(t) + \bar{j}_\ell(t)}{\bar{n}_i(t)} \tag{6}$$

where $\bar{j}_\ell(t)$ is the expected number of new jobs created in grade ℓ in (t,t+1). Two things are very important in Equation 6. The first is the cumulative impact or chain reaction of vacancies originating in higher grades. This chain reaction results from the initial vacancies being filled by someone inside the organization who thereby opens another vacancy. Secondly, an individual's promotion chances over time are postulated as the ratio of the number of vacancies to the number of persons available for promotion or, in other words, the ratio of demand and supply over time.

---

[4] We will use the following symbols to indicate alternative meanings: $\bar{x}$: expected value of x; $\hat{x}$: value of x estimated from observed data; x: observed or theoretical value of x.

Since new vacancies, $\bar{j}_l(t)$, are an expected or derived term, there must be some mechanism for allocating the total pool of new jobs to grades. The simplest case, which we will use here, is to assume constancy in relative grade size. Let overall growth in jobs in (t,t+1) be J(t);

then
$$\bar{j}_l(t) = J(t)\hat{\rho}_l \qquad (7)$$
where
$$\hat{\rho}_l = \frac{\sum_t n_l(t)}{\sum_t \sum_l n_l(t)}, \qquad (8)$$
the proportion of persons in the ILM holding jobs at grade j. If we take the total ILM size at time t, N(t), as observed, then

$$J(t) = N(t+1) - N(t). \qquad (9)$$

Managerial selection rules. We now add two important factors to the supply/demand nature of the model: an assumption of managerial decision-makers who play an active role in the mobility process and an assumption that the managerial selection rules for labor supply are conditional on vacancies.

The discussion of individual heterogeneity, in this instance grade-level seniority, will be presented with respect to a person having seniority s in grade i. Let $v_{i+1}(t)$ represent the total number of vacancies in grade i+1 in (t,t+1). Given a vacancy, the managerial staff in grade i+1 may choose to fill it internally or externally. Let $\ell_{i+1}(t)$ denote the probability of filling a vacancy internally (in this case, by a person from grade i). If we assume a constant managerial policy regarding this internal/external distribution, the estimate of ℓ_{i+1i} is

$$\hat{\ell}_{i+1} = \frac{\sum_t \sum_s n_{i,i+1}(s,t)}{\sum_t v_{i+1}(t)}, \qquad (10)$$

where $n_{i,i+1}(s,t)$ is the observed number of persons with seniority s in grade i at time t who are promoted to grade i+1 by time t+1.

For internal selections, we assume that the managerial preference for an individual is determined by his seniority level within the grade.[5] We further assume that this selection rule is constant as long as there is a sufficient supply of individuals with the desired seniority to meet the vacancy requirement. Hence, given that a vacancy in grade i+1 is to be filled internally, the chances of being selected for promotion for a person with seniority s in grade i is $\lambda_{i+1,i}(s)$ and

$$\hat{\lambda}_{i+1,i}(s) = \frac{\sum_t n_{i,i+1}(s,t)}{\sum_t n_{i,i+1}(t)}. \qquad (11)$$

When there is an insufficient supply at a seniority level, the above selection rule must be modified so that no vacancies remain unfilled at the end of this period. If we assume that the relative weights attached to each seniority level are invariant, we may operationalize this modification by simply renormalizing the $\hat{\lambda}_{i+1,i}(s)$ terms. That is, $\hat{\lambda}_{i+1,i}(s)$ is applied iteratively until all vacancies are filled. Such modifications of the λ's are necessary when the seniority supply is less than the internal demand[6]—

$$n_i(s,t) < v_{i+1}(t)\ \ell_{i+1}\ \lambda_{i+1,i}(s). \qquad (12)$$

The choice of filling a vacancy internally or externally modifies the chain reaction of vacancies depicted in Equation 6 since some promotions are truncated by lateral recruitment. This modification is captured in Equation 13;

---

[5] Many alternative assumptions about heterogeneous attributes of the population, in terms of decision rules for managerial selection, are possible; thus, we expect other population attributes to affect both managerial and worker decisions. Since the present data preclude examining attributes other than seniority, however, our discussion will be directed only to seniority effects. Moreover, once multiple attributes are considered, then extreme partitioning, such as in McFarland's (1970) Markovian model, requires use of multivariate modeling strategies as in the Markovian regression models of Spilerman (1972), Wise (1975) and Tuma (1976), rather than partitioning of state space as is used here.

[6] Operationally, this means checking the promotion pool for sufficient supply via Equation 12. If $n_i(s^*,t)$ is less than the desired number, then all $n_i s^*,t)$ are promoted and $\{\lambda_{ii}(s)\}$ is renormalized to fill the vacancies remaining from the inequality in Equation 12; that is, $\lambda_{ii}(s) = \dfrac{\lambda_{ii}(s)}{[1 - \lambda_{ii}(s^*)]}$, where s* denotes the specific seniority level with insufficient supply.

$$
\begin{aligned}
\bar{v}_i(t) &= \sum_s \bar{n}_i(s,t)\ \bar{p}_{io}(s,t) \div \bar{j}_i(t) \qquad \text{if } i = k \\
&= \hat{\ell}_{i+1}\ \bar{v}_{i+1}(t) + \\
&\quad \sum_s \bar{n}_i(s,t)\ \bar{p}_{io}(s,t) + \bar{j}_i(t) \qquad (13) \\
&\qquad\qquad \text{if } i = 1, \ldots, k-1 .
\end{aligned}
$$

In sum, let m denote an individual in the ILM. Then, the probability of m being promoted, $\bar{p}_{i,i+1}(m)$, is

$$
\Pr\left[\begin{array}{l} \text{m is in} \\ \text{grade } i+1 \text{ at} \\ \text{time } t+1 \end{array}\middle|\begin{array}{l} \text{m is in} \\ \text{grade } i \text{ at} \\ \text{time } t\ , \end{array}\ \begin{array}{l} \text{m has} \\ \text{seniority } s \\ \text{in grade } i\ , \end{array}\ \begin{array}{l} \text{there is a} \\ \text{vacancy available} \\ \text{in grade } i+1\ , \end{array}\ \begin{array}{l} \text{the vacancy} \\ \text{is to be filled} \\ \text{internally} \end{array}\right]
$$

$$
= \frac{\bar{v}_{i+1}(t)\ \hat{\ell}_{i+1}\ {}^{-}\lambda_{i+1,i}(s)}{\bar{n}_i(s,t)} . \qquad (14)
$$

Worker exit decisions. We treat exit decisions as conditional on both the seniority distribution and promotion rates. We assume a two-step decision process in which managerial promotion occurs first and then exit behavior, contingent on managerial decisions, is determined. Sequencing the process in this manner is consistent with an individual anticipating promotion and not initiating job search (or at least not accepting outside offers) until internal decisions are made. We assert that normative expectations regarding promotion will have an effect on exit behavior once the promotion outcomes are known. We expect exits to be inversely related to internal opportunities. That is, that if promotion opportunities increase, exit rates will drop and if the opportunities decrease, exit rates will rise in response.[7] Here we conceptualize a process which generates this type of response behavior.

Consider two types of decision-makers (managers, workers) and two types of decisions (promotion, exit). Assume the original set of persons in grade i at the start of each time interval, $n_i(t) = \sum_s n_i(s,t)$, is the promotion pool from which managers make selections. Assume that the workers await the outcome of promotion decisions before making a decision to exit. This reduces the second set of decision-makers (workers) to

$$
\bar{n}_i^*(t) = n_i(t) - \bar{n}_{i,i+1}(t) . \qquad (15)
$$

Thus, the exit probability is now conditional on the individual's promotion chances. Moreover, since the distribution of labor supply does not always equal labor demanded, the seniority distribution of the available promotion pool also has an effect on behavior.

Again, denoting the individual as m, the estimate of the conditional probability of exiting, $\hat{p}_{io}^*(m)$ is

$$
\Pr\left[\begin{array}{l} \text{m exits} \\ \text{between} \\ \text{time } (t,t+1) \end{array}\middle|\begin{array}{l} \text{m is in} \\ \text{grade } i \text{ at} \\ \text{time } t\ , \end{array}\ \begin{array}{l} \text{m has} \\ \text{seniority } s \\ \text{in grade } i\ , \end{array}\ \begin{array}{l} \text{m was not} \\ \text{selected for} \\ \text{promotion} \end{array}\right]
$$

$$
= \frac{\sum_t n_{io}(s,t)}{\sum_t n_i^*(s,t)} . \qquad (16)
$$

The desired directional effects on exit behavior may be easily shown. Assume a constant promotion pool of 100 and an estimate of conditional exit as $p^*_{io}(t) = .125$ in a prior period in which there were 20 promotions and 10 exits. In the time period (t, t+1), there are also 20 promotions. Hence, $n^*_i(t) = 80$. Therefore, the model predicts the same number of exits, $n^*_i(t)\ p^*_{io}(t) = 80 \times .125 = 10$. Let opportunities decrease to 10 promotions in the time interval (t+1, t+2). Then the model predicts 11 exits in response. Similarly, let opportunities increase to 30 promotions in the period (t+2, t+3). Then the model predicts 9 exits, a decrease in loss rate. The derived exit rates for the initial population per time period are thus .10, .11

---

[7] Since external supply and demand are not treated here, we assert no specific external effects. The behavioral effects are, therefore, assumed ceteris paribus. It is reasonable to expect, for example, that an individual's exit probability is affected by the external supply of jobs relative to his internal opportunities.

and .09 as opportunities are constant, decrease and increase, respectively.

Having postulated the exit process as conditional on promotions, we may now specify the derived unconditional exit probabilities of Equations 6 and 13:

$$\bar{p}_{io}(s,t) = \hat{p}^*_{io}(s)\,[1-\bar{p}_{i,i+1}(s,t)]\,. \quad (17)$$

Stayers. Finally, once the population of unpromoted stayers is determined, these individuals are assumed to "age" in seniority by one time period. For this remaining population, a simple demographic aging process is assumed. The derived probablities for this "staying" process are, however, determined by the prior promotion and exit events.

Recruitment. In an ILM with recruitment at all grades, the recruits would diminish the number of chain reactions of promotion opportunities, as depicted in Equation 13. In which case, as noted earlier, managerial selection decisions between internal and external labor supply become an important issue. In the ILM that we examine, recruitment occurs only at the bottom grade, thus simplifying the process, namely, $\ell_j=1$ for j > 1. Recruitment is simply

$$\bar{R}_1(t) = \bar{v}_1(t)$$

$$= \sum_{l=1}^{k} \sum_{s} \bar{n}_l(s,t)\,\bar{p}_{lo}(s,t) + \bar{j}_l(t)\,. \quad (18)$$

The manner in which the overall demand model is formulated—where entering vacancies open vacancies through lower grades—means that the model's predictions must be sequentially derived from the highest to the lowest grade. Moreover, the built-in priorities for checks on adequacy of labor supply to meet demand and the formulation of exits as conditional on promotions also means deriving promotions prior to exits within each grade. The derivation of promotions is rather direct—from available vacancies and seniority selection rules. The derivation of staying probabilities is more complex, however, having been constructed from a two-step process of promotions and exits that are conditional on promotions. Thus, given the new exit specification, all transition probabilities become interrelated—promotions affect exits within the same grade and these conditional exits affect promotion opportunities in lower grades due to the chain reaction of opportunities depicted in Equations 6 and 13.

Markovian Labor Supply Models

The Duration Markov Chain (DMC) Model

As the simplest and most natural Markovian model of seniority flows, we suggest the Cornell model, developed by McGinnis (1968) and Henry et al. (1971). This model is an important advance over simple Markovian models which assume population homogeneity and stationarity of transition probabilities. In tests of the axioms of cumulative inertia (Morrison, 1967; Land, 1969) and of destination-duration independence (Ginsberg, 1977), the model's underlying assumptions have generally been supported in studies of geographical mobility. However, very little is known concerning its utility for predicting labor movement.

Whether supply attributes, such as seniority, are sufficient to predict organizational behavior or whether some internal opportunity-supply combination, as in the labor demand model, are more accurate will be empirically tested later. At the highest grade, from which there is no internal promotion, the two models will have the same exit parameter. But, since the "selection" process into the highest grade differs radically, predictions even in the highest grade will differ. The demand model makes selections to fill a specified set of vacancies in grade k; the duration-specific Markovian model, on the other hand, makes selections proportional to the available supply in grade k−1, while ignoring vacancies in grade k.

Since all seniority specific transition probabilities are assumed to be constant in this first Markovian model, we drop the time argument from the transition terms. The model is simply

$$\hat{p}_{ij}(s) = \frac{\sum_t n_{ij}(s,t)}{\sum_t n_i(s,t)}\,, \; j = i,\ i+1 \text{ and } o\,. \quad (19)$$

For individual m, we have $p_{ij}(m)$, as

$$\Pr\left[\begin{array}{l|ll} \text{m is in} & \text{m is in} & \text{m has} \\ \text{state j at} & \text{grade i} & \text{seniority s} \\ \text{time t+1} & \text{at time t,} & \text{in grade i} \end{array}\right]$$

$= \hat{p}_{ij}(s)$ for state $j = i, i + 1$, and o, which indicates staying in grade i, being promoted to grade $i + 1$ and exiting to the outside. For a lucid matrix presentation of this duration Markov chain (DMC) model, see Henry et al. (1971).

Growth and recruitment. To complete the model, we must account for organizational growth and recruitment. Since all internal staffing is specified by the seniority specific transition probabilities, $\{p_{ij}(s)\}$, the remaining task is to allocate recruitment. In the organization we examine, all recruits enter at the bottom,[8] which simplifies our task: we take total ILM size, N(t), as observed, as in the opportunity labor demand (OLD) model. Thus recruitment at the bottom, $R_1(t)$, during year t is assumed to be

$$\bar{R}_1(t) = N(t+1) - \sum_i \sum_s \bar{n}_i(s,t+1)\ . \qquad (20)$$

The Organizational Markov Chain (OMC) or Constant Push Model

As an alternative to the DMC model which allocates promotions and exits in proportion to the supply at the individual seniority level, we propose a simple Markovian model with stationary promotion rates, corresponding to a more stable process at the *organizational* level. Given grade specific promotion probabilities, selection by seniority occurs analogous to the labor demand model. This model has some plausibility in that, contrary to common impressions of sociologists regarding the failure of the simple Markov chain (MC), most tests of the simple MC model in organizational ILMs have found the model reasonably satisfactory. Evidence for the model's support has been found in the following ILMs: higher education (Young, 1965), manufacturing (Young, 1965; 1971), private research and development (Young, 1965), governmental scientists (Sales, 1971), a women's military unit (Forbes, 1971), the large civilian work force supporting the U.S. Navy (Charnes et al., 1972) and a state police organization (Stewman, 1975b). When tested against vacancy models (Young and Vassiliou, 1974; Stewman, 1978), the simple MC model with homogeneous populations has fared less well. We stress that it is in such comparative tests that the model's adequacy must be determined—not in individual tests across multiple ILMs.[9]

The simple MC must be modified to specify internal selection. Thus, while we assume the internal movement is Markovian at the aggregate grade level, it will no longer be Markovian at the seniority level. This is the opposite of the DMC model presented earlier, where the grade specific seniority mobility remained Markovian, but the aggregate level process was no longer a Markov chain.

Managerial selection rules. First, assume promotion probabilities are constant. That is,

$$\hat{p}_{i,i+1} = \frac{\sum_t \sum_s n_{i,i+1}(s,t)}{\sum_t \sum_s n_i(s,t)}\ . \qquad (21)$$

Second, assume managers select persons to be promoted according to a decision rule keyed to seniority as in the labor demand model,

$$\hat{\lambda}_{i+1,i}(s) = \frac{\sum_t n_{i,i+1}(s,t)}{\sum_t n_{i,i+1}(t)}\ . \qquad (22)$$

Thus, to derive an individual's promotion chances from this model, we observe that

$$\bar{n}_i(s,t)\bar{p}_{i,i+1}(s,t) = \bar{n}_i(t)\ \hat{p}_{i,i+1}\ \hat{\lambda}_{i+1,i}(s). \qquad (23)$$

---

[8] If lateral recruitment is allowed at all grades, then the extent of recruitment per grade must also be specified. In none of the three models we examine is this necessary since recruitment is entirely at the bottom grade.

[9] Furthermore, we wish to correct an impression of sociologists that simple Markov chains have always resulted in predictive failures. This impression arises from reading only tests conducted on cohort populations in the U.S. Most, but not all, tests of organizational ILMs cited above, and in which a continuously operative labor market process is represented, have been conducted in Europe and generally in the U.K. At issue is simply the proposition that we make conclusions regarding the simple MC on the basis of the evidence.

The model's prediction is, therefore,

$$\bar{p}_{i,i+1}(s,t) = \frac{\bar{n}_i(t)}{\bar{n}_i(s,t)}\, \hat{p}_{i,i+1}\, \hat{\lambda}_{i+1,i}(s) = \frac{1}{\bar{\alpha}_i(s,t)}\, \hat{p}_{i,i+1}\, \hat{\lambda}_{i+1,i}(s) \quad . \qquad (24)$$

Of course, the relative distribution of seniority in grade i, $\alpha_i(s,t)$, is observed only at the beginning of the first time period and is derived thereafter. The model asserts that one's promotion chances vary over time in response to the distribution of seniority in the promotion pool. That is, as the relative size of the individual's seniority level declines, the individual's promotion chances improve and vice versa. These changes result from the assumptions of constant grade promotion probabilities and managerial selection rules. As in the labor demand model, there is a possibility of an insufficient supply. In such a case, $\hat{\lambda}_{ji}(s)$ is renormalized iteratively until the supply is adequate to satisfy the aggregate parameter, $\hat{p}_{ij}$.

Worker exit decisions. Just as in the labor demand model, a two-step decision process is postulated. That is, we assume workers await the managerial promotion decison before deciding whether or not to leave. The conditional exit probability is thus given by Equation 16. Since this model and the labor demand model differ in the derivation of promotion probabilities, the populations of workers making exit decisions in the two models will also differ; this result yields different unconditional exit probabilities for the initial worker population.

Growth and recruitment. Growth is accommodated the same way by both Markovian models. That is, all upper grade movement is generated, reallocating persons per grade. Since total ILM size is taken as observed, the remaining staff to meet growth and replacement requirements is recruited at the bottom grade via Equation 20.

Parametric Comparison of the Models

A brief overview of the basic parameters and derived terms differentiating the three models is shown in Table 1. Only terms which will be used in the remainder of the paper are presented. The first three terms, which relate to jobs or job vacancies, are treated only in the OLD model. Internal managerial selection rules are explicit in the OLD and OMC models, but not in the DMC model. Flow parameters at the individual seniority level $\{p_{ij}(s)\}$ are estimated from observed data in the DMC model, but are derived terms in the OMC and OLD models. The characteristics that distinguish the derived flows in the OLD and OMC models may be seen in the last row, where the grade-level promotion probabilities are estimates from observed data in the OMC model, but derived (as the ratio of vacancies to labor supply) in the OLD model.

Table 1. Comparison of Parameters and Derived Terms**

	OLD	OMC	DMC
Allocation of new jobs	$\hat{\rho}_i$	—	—
New jobs	$[\bar{j}_i(t)]$	—	—
Job vacancies	$[v_i(t)]$	—	—
Managerial selection rules	$\hat{\lambda}_{i+1,i}(s)$ $\hat{\ell}_{i+1}$	$\hat{\lambda}_{i+1,i}(s)$	—
Conditional exit	$\hat{p}^*_{i,o}(s)$	$\hat{p}^*_{i,o}(s)$	—
Unconditional exit	$[\bar{p}_{i,o}(s,t)]$	$[\bar{p}_{i,o+i}(s,t)]$	$[\hat{p}_{i,o+o}(s)]$
Promotion	$[\bar{p}_{i,i+1}(s,t)]$	$[\bar{p}_{i,i+1}(s,t)]$	$[\hat{p}_{i,i+1}(s)]$
Stay	$[\bar{p}_{i,i}(s,t]$	$[\bar{p}_{i,i}(s,t)]$	$[\hat{p}_{i,i}(s)]$
Grade level	$[\bar{p}_{i,i+1}(t)]$	$\hat{p}_{i,i+1}(t)$	$[\bar{p}_{i,i+1}(t)]$

* Estimated term $\hat{X}$.

** Derived term $[\bar{X}]$.

The feature which differentiates most among the models is each model's view of the underlying process generating promotions. This may be seen by a direct comparison of the promotion equations. The difference in treatment of managerial selection rules is also apparent. These equations are:

Model Promotion Equations: $\hat{p}_{i,i+1}(s,t)$

DMC: $$\frac{\sum_t n_{i,i+1}(s,t)}{\sum_t n_i(s,t)}\quad p_{i,i+1}(s)\ \forall\ t$$

OMC: $$\frac{\bar{n}_i(t)\hat{p}_{i,i+1}\ \hat{\lambda}_{i+1,i}(s)}{\bar{n}_i(s,t)}$$

OLD: $$\frac{\left\{\sum_{\ell=i+1}^{k}\ \sum_s \bar{n}_\ell(s,t)\bar{p}_{\ell o}(s,t)+\bar{j}_\ell(t)\right\}\hat{\lambda}_{i+1,i}(s)}{\bar{n}_i(s,t)}$$

3. DATA AND PARAMETER ESTIMATES

The ILM Data

In a formal organization such as the state police, there are several internal labor markets: clerical, business administration, computer programming, and maintenance (all of which are civilian in nature) and a separate police ILM. There is no exchange of staff between the police and any of the civilian ILMs. Thus, we focus only on the police segment of the organization.

The data were obtained from individual career records and extend from January, 1950 to January, 1970. Parameter estimates are made from the first ten years (1950–1959) and the tests cover the second decade (1960–1970).

State Definitions and Parameter Estimates

The state police system has a clearly defined authority and status structure. On the basis of numbers and substantive meaning of authority-status levels, the nine formal ranks were grouped into five grades. They are (1) COL: Colonel, Lt. Colonel, Major, Captain, Detective (Det.) Captain; (2) LT: Lieutenant (Lt.), Det. Lt.; (3) SGT: Staff Sergeant (S/Sgt.), Det. S/Sgt., Sgt., Det. Sgt.; (4) CPL: Corporal, Det., and (5) TPR: Trooper. The number of seniority levels chosen per grade were based on population size and on nonstationarity between seniority levels of the DMC parameter estimates. For the COL and LT grades, six seniority levels were chosen: Seniority 1 (S1) through 5 and Seniority 6 or above (S6+). SGT has S1 to S8+; CPL S1 to S10+; and TPR S1 to S17+.

We first present the parameter estimates which do not take into account seniority levels. The data for estimation are from the years 1950–1959. From Equation 8 the estimates of new job vacancy allocations per grade, $\hat{\rho}_j$ in the OLD model, are as follows:

COL	LT	SGT	CPL	TPR
.0192	.0220	.0989	.1940	.6659.

Also, using Equation 21, the estimates of the aggregate grade promotion probabilities in the OMC model, $\hat{p}_{i,i+1}$, are

TPR→CPL	CPL→SGT
.0480	.0932
SGT→LT	**LT→COL**
.0688	.1517 .

Table 2 provides the maximum likelihood estimates (MLE) of the annual transition matrix for the DMC model estimated from Equation 19. Standard errors (se) of estimation are also provided for the promotion and exit probabilities. The formulae for the se values are

$$\mathrm{se}\{\hat{p}_{ij}(s,t)\} = \left[\frac{p_{ij}(s,t)[1-p_{ij}(s,t)]}{n_i(s,t)}\right]^{1/2} . \qquad (25)$$

(See Forbes, 1971.) Staying rates are computed as residuals. The range of variation (maximum-minimum) for promotions by seniority level, not including the required waiting periods in SGT, CPL and TPR, is substantial within each grade—LT: .29, SGT: .14, CPL: .21, TPR: .50. Seniority effects on promotion are obviously clear and quite important.

The seniority specific promotion curves for each grade are shown in Figure 1. The vertical lines above and below each expected probability indicate one standard error of estimation. Thus, while we observe at least one dip in each mean value curve, which produces a bimodal distribution, the standard errors show the promotion rates to form easily a skewed, unimodal, inverted U-shaped curve at each grade, and bear out McGinnis's (1968) hypothesis.[10]

Figure 2 shows the expected behavior of the promotion process across grades. As an individual rises in the hierarchy, his promotion chances peak at lower seniority levels, suggesting an *acceleration effect* of hierarchical grade. That is, one's best promotion chances come earlier, the higher the grade. Moreover, the rise and fall in promotion probabilities over seniority levels within a grade does not easily fit the argument of constant transition probabilities at the individual level. It does suggest an experience effect as measured

---

[10] All but three probabilities lie within one standard error of this form of curve (see dotted line); however, only 7 in 10 points are expected to be within this range.

†† Equation [25].

by seniority. With regard to the expected promotion behavior per grade, we observe the following from the estimates: (1) LT: discounting the S5 values somewhat (due to the small N and associated high standard error), there is a very rapid increase in promotion chances from S1 to S2; then the probabilities decrease. At S2, one's promotion chances are 25%; (2) SGT: there is a rapid increase in the third year, peaking in the fifth year, S5, at 15%; (3) CPL: there is a gradual increase in promotion chances until the fifth year, then a rapid jump peaking in the seventh year,

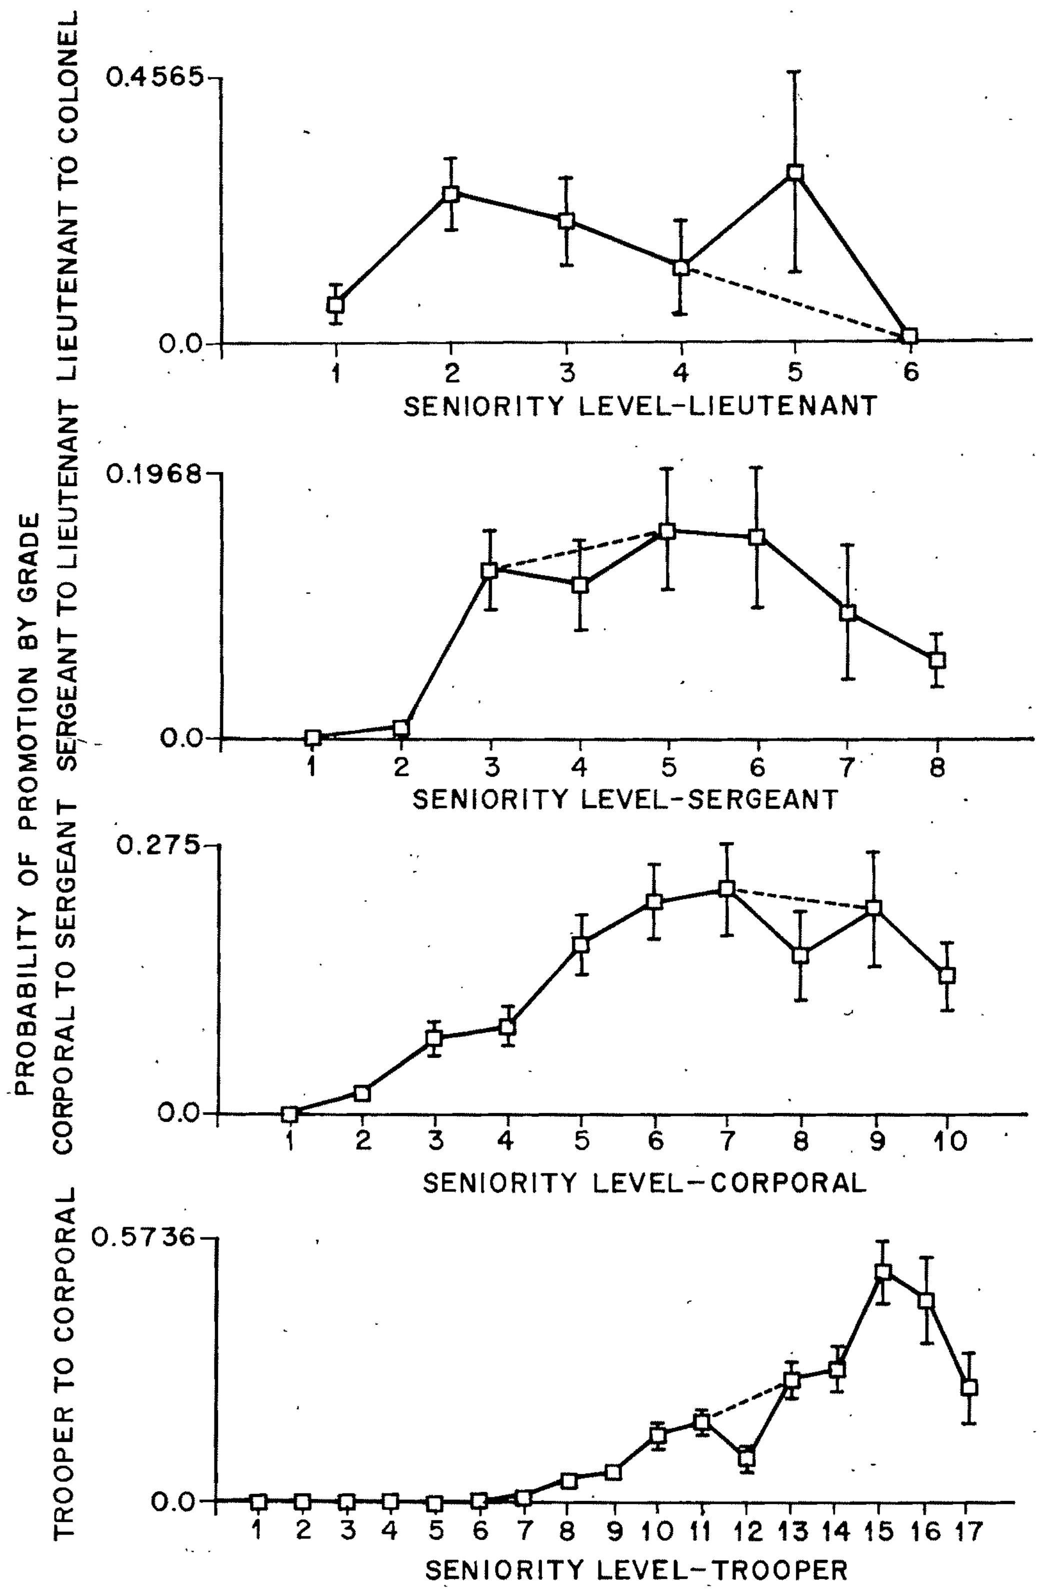

FIGURE 1. Promotion Probability Distribution by Grade (1950-59)

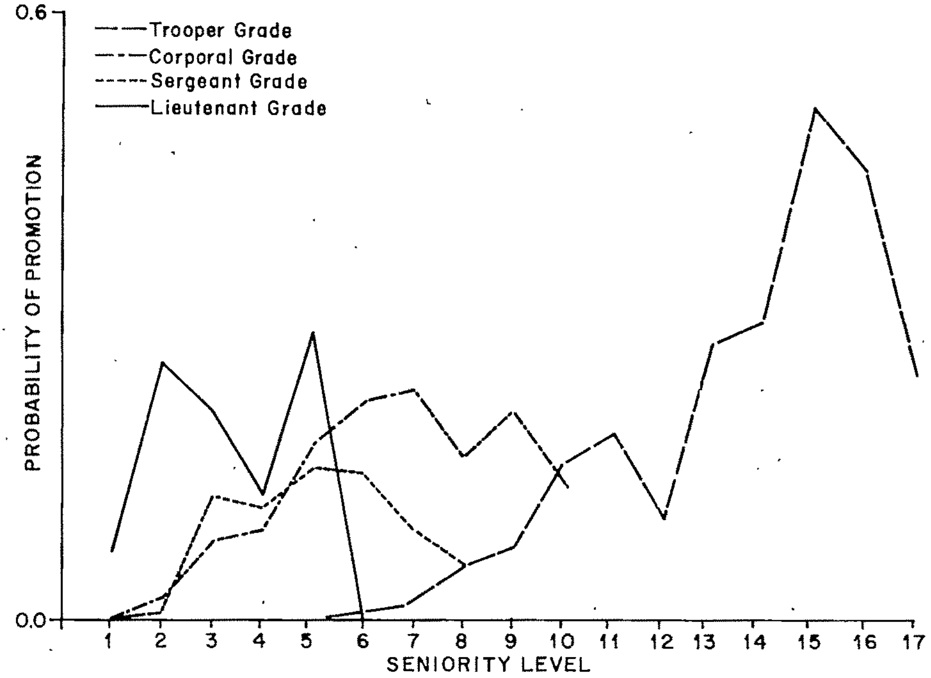

FIGURE 2: Promotion Probability by Grade and Seniority for the Entire Organizational ILM (1950-59)

S7, at 23%; (4) TPR: there is a waiting period of five years, then a gradual increase until the tenth year, with a peak at the fifteenth year, S15, when 51% are promoted.

The estimates of the managerial selection rules and conditional exits for the OLD and OMC models are given in Table 3. The $p^*_{10}(s)$ estimates at the COL grade are the same as the $p_{10}(s)$ estimates of the DMC model since there are no promotions from the highest grade. Thus, the table includes only four grades for both managerial selection and conditional exits. As in the promotion estimates of the DMC model, the managerial selection probabilities differ greatly between seniority levels. The range of variation within each grade, not including required waiting time, is as follows—LT: .48; SGT: .27; CPL: .14; and TPR: .16. The smaller variation in the lower grades contrasts with the pattern found in the DMC probability estimates and the variation in the upper grades is much higher here.

Figure 3 presents the managerial selection probability distributions. The image one receives of how the individual promotion process operates is quite different from that of the DMC model. In the OLD model, the managerial selection rules may be interpreted in the following way: given a vacancy, what is the probability that a manager decides to fill it with an individual having seniority level s? The OMC model's interpretation of this parameter differs in one important way: given a promotion, what is the probability that a manager decides to promote an individual with seniority s? For the present analysis of the models, with no lateral recruitment, this difference in interpretation seems minor. However, in ILMs with lateral recruitment, the managers in the OLD model can choose to fill the vacancy internally or externally. No such choice exists in the OMC model since vacancies are not conceptualized. Thus, the distinction we draw between the meanings of the selection rules in the OLD and OMC models depicts an important difference in viewpoints regarding the underlying managerial selection process. For convenience here, we will discuss the expected managerial decision rules using the vacancy model interpretation. *The* $\hat{\lambda}_{jl}(s)$ *estimates form a probability distribution of managerial preference across seniority*

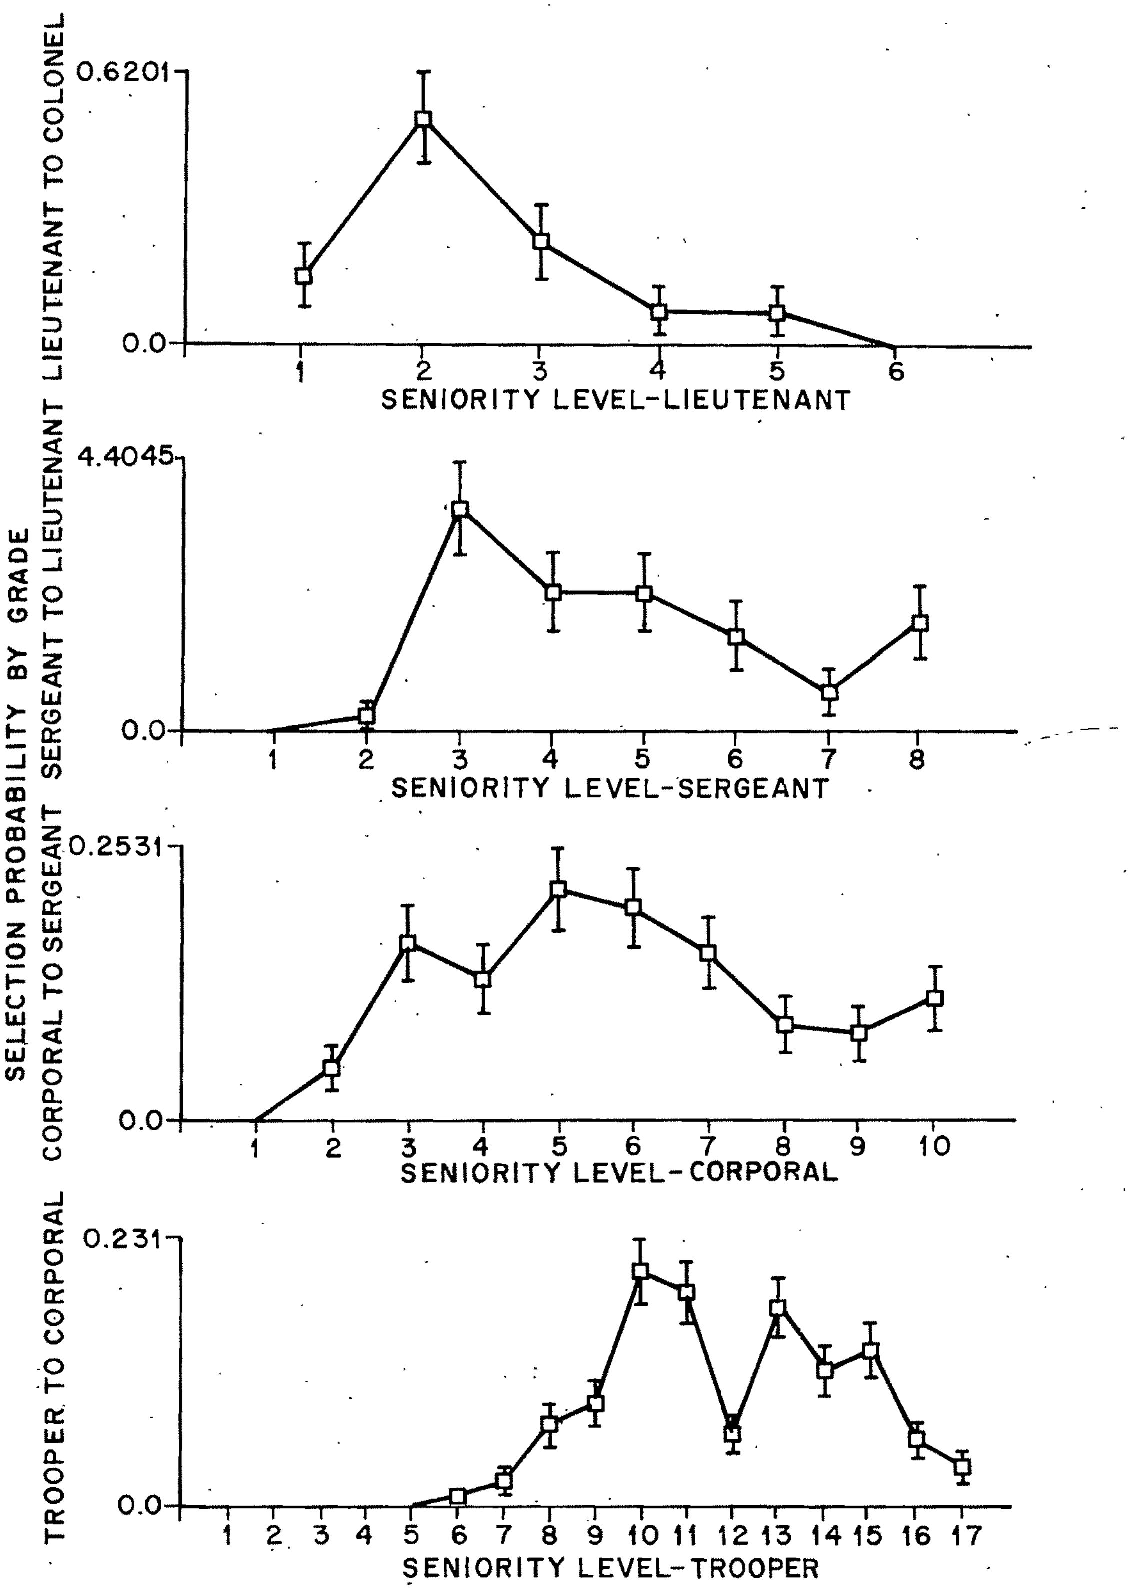
levels. At the LT grade there is a 48% chance of selecting from Seniority 2 (S2) and a 70% chance of the selection being from S2 or S3, which indicates a very narrow selection band. Selections from the SGT grade are also concentrated (80%) from S3 to S6 with the largest being from S3 (29%). In the CPL grade there is a somewhat greater dispersion with selection probabilities .18 and .16 for S5 and S6, respectively. Finally, selections from the TPR grade are once again more concentrated, with the greatest preferences for S10 and S11 (17 and 16%, respectively). Given the standard error of estimation, it is plausible that these estimates have an underlying *unimodal distribution*. It is also interesting to observe that an *acceleration effect* of hierarchical grade as seen in the DMC model is also obtained here. What varies from the DMC model estimates is the behavior of the curve—lower seniority levels having higher probabilities—and, of course, the meaning of the probabilities. The selection probabilities (λ's) refer to selectivity from the entire grade promotion pool whereas the DMC promotion probabilities ($p_{i,i+1's}$) are based only on the number of persons within the individual's own seniority level. Thus, in regard to the acceleration effect, one's best selection chances occur earlier, the higher the grade.

To make direct comparisons between the different ways of modeling the process, we must have analogous "managerial selection rules" for the DMC model. The OLD and OMC models assume that managerial selection across seniority levels is stable and that the promotion and exit probabilities within seniority levels vary over time. Conversely, the DMC model assumes that promotion and exit probabilities within seniority levels are stable and that managerial selection across seniority levels varies over time (in response to fluctuations in the seniority distribution within grade). The derived managerial selection rules *across* seniority levels for the DMC model are obtained from the following equation:

$$\bar{\lambda}_{i+1,i}(s,t) = \frac{\bar{n}_{i,i+1}(s,t)}{\sum_s \bar{n}_{i,i+1}(s,t)} = \frac{\bar{n}_i(s,t)\ \hat{p}_{i,i+1}(s)}{\sum_s \bar{n}_i(s,t)\ \hat{p}_{i,i+1}(s)}. \tag{26}$$

Figures 4–6 provide illustrative comparisons between the models' descriptions of the process for the SGT grade. Figure 4 shows the variation between models in the



IGURE 3. Managerial Selection Probability Distribution by Grade (1950-59)

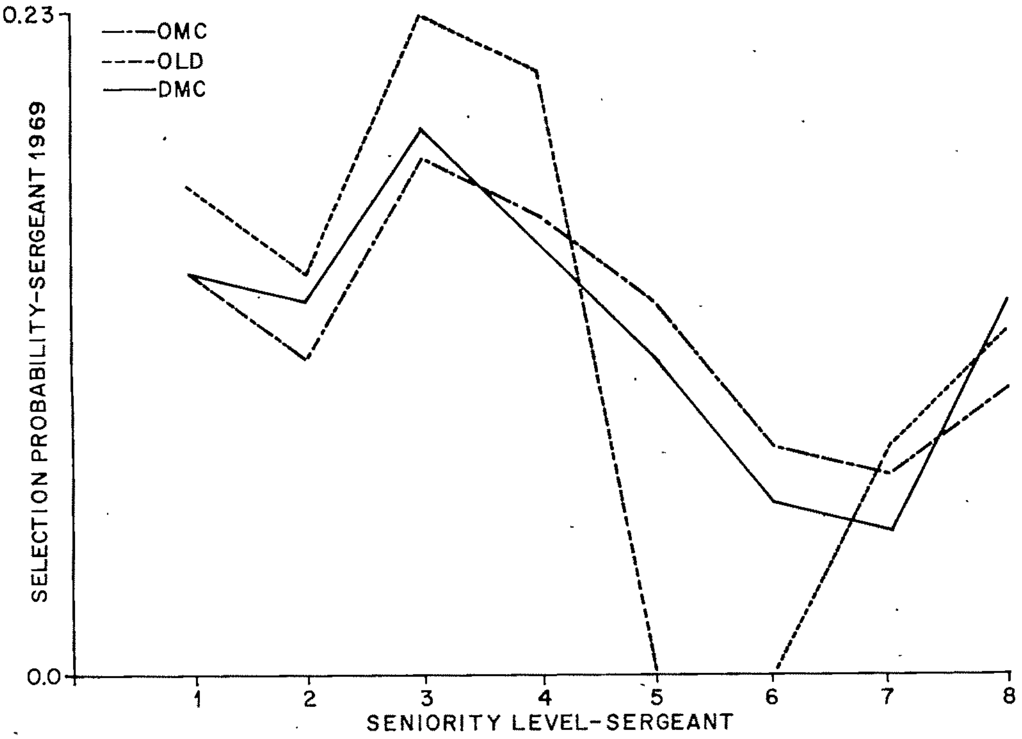


FIGURE 4: Managerial Selection Probability Distribution for SGT: by Model (1969)

distribution of managerial selection probabilities (λ's). The OLD and OMC models differ in this case since the λ estimates are renormalized (see fn. 5) due to the labor supply constraint (Equation 12) in the OLD model. In general, the form of the curves is similar, with greater differences between the OLD model and the DMC and OMC models. All models show S5 to have the highest managerial preference. Figures 5 and 6 reveal radical differences in the models' predictions and, in particular, show the expected nonstationarity of the seniority specific promotion probabilities of the OLD and OMC models. The large differences in Figure 5 indicate the effect of postulating a contingent managerial decision process, as in the OLD and OMC models, vs. a direct supply process as in the DMC model. Much larger promotion probabilities occur in the OLD and OMC models (at S5) when the supply of individuals in a seniority level is near the number of vacancies that the managerial preference function assigns to that level. Figure 6 shows the effects of insufficient seniority supply at S5 and S6 for the OLD model; note the volatile response of the promotion probabilities at S4 and S7 as unfilled vacancies are reassigned to other seniority levels.

4. COMPARATIVE TESTS

The tests extend over a 10-year period, 1961–1970, with parameters estimated from the prior 10 years, 1950–1959. All three models are given exactly the same observed information, although it is used differently within each model. For the parameter estimates, these observations are simply $n_{ij}(s,t)$, $j = i, i+1, o$. And, in the tests, two types of observed data are used—the starting seniority distributions at each grade in 1960, $n_i(s,1960)$ and the total organization size for all 10 years, $N(t)$. From 1961 to 1970, all grade and seniority distributions within grade are derived. That is, while the 1961 prediction is based on the 1960 observed values, the 1962 forecast uses the 1961 prediction; the 1963 forecast uses the 1962 prediction, and so on. Therefore, predictions in 1963 and 1970 involve a 3-year and 10-year forecast, respectively. These tests are commonly called n-step tests, where the

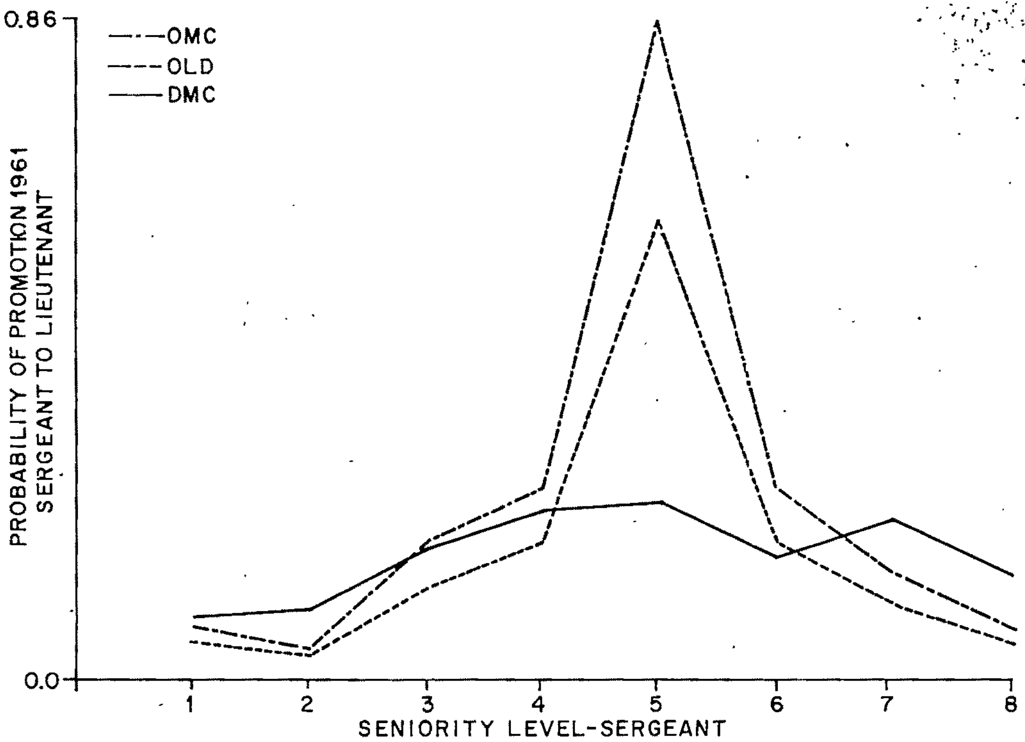

FIGURE 5: Promotion Probability by Seniority Level for SGT: 1961

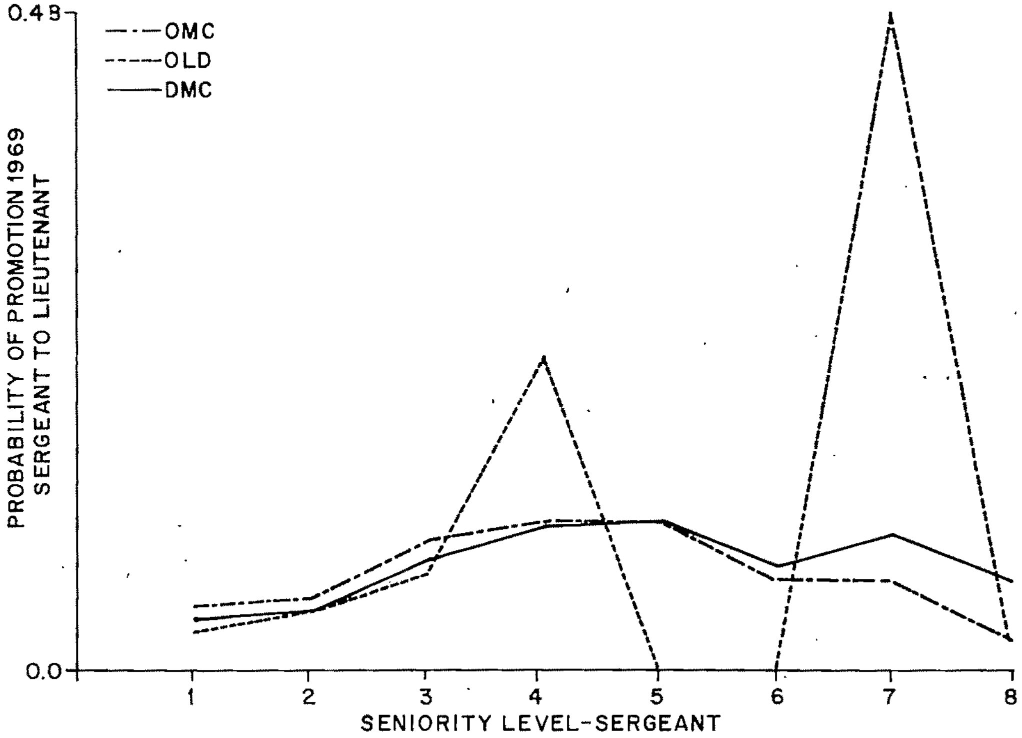

FIGURE 6: Promotion Probability by Seniority Level for SGT: 1969

prediction for the nth year is based on the predicted distributions for the (n-1)st year. This is a much more rigorous test than a set of n 1-step tests. For brevity, we focus on results of the 3-, 5- and 10-step predictions and on the average predictive capability of each model after 3, 5 and 10 years.

Table 4 presents the predicted and observed seniority distributions within grade for the 3-, 5- and 10-step tests and Table 5 provides summary measures.

	OLD	.45	.56	.14	.46	.22	.37

[a] Equation [27].

[b] With equal weights per grade.

We utilize a measure which equally penalizes each predictive error within a grade—both overpredictions and underpredictions—and weights seniority levels by size. The measure per grade is

$$\frac{\sum_s | P_s - O_s |}{\sum_s O_s}, \qquad (27)$$

where P_s is the predicted number of persons with seniority s and O_s, the observed number. The observed term is used in the denominator since it is constant across different models. We interpret the measure calculated by Equation 27 as the average percentage error per seniority level within the grade. After 3 years, the OLD model predicts better at each grade and the OMC model is slightly more accurate than the DMC model. In only one grade, TPR, is the DMC model better than the OMC model. After five years, the same relative standing exists: OLD > OMC > DMC. However, at 10 years, the OMC and OLD models' errors in the CPL and TPR grades are much larger than those of the DMC model. If equal weights are assigned to all relative grade errors, however, the same ranking in all three years holds: OLD > OMC > DMC. In fact, for the 15 predictions, only three predictions are better than that of the OLD model—COL grade in 1965 and CPL and TPR grades in 1970. For these 3-, 5- and 10-year predictions, the OLD model clearly has the best overall fit.

A different perspective is gained if we also compare the models' predictions for aggregate grade distribution obtained from the seniority predictions. That is, rather than concentrate on an individual's seniority level by grade, we take a more aggregate look and simply predict an individual's grade. These predictions and the relative errors per grade are given in Tables 6A and 6B. As expected, the errors are much lower and the same comparative finding remains.

As the time horizon is extended, we may also be interested in the consistency of a model's predictive accuracy over the entire time period. Evaluating overall consistency means utilizing all one-point, n-step (n = 1,...,10) predictions rather than a few of them. To do so, we use a summary measure of the average predictive error within a time period. Three-, five- and ten-year periods are taken, which correspond to the 1-point tests

Table 6A. Predicted and Observed Grade Distributions for Three, Five and Ten Years

[b] With equal weights per grade.

above. The ten-year average allows comparison across models for the full time period. The 3- and 5-year data are shown to illustrate the models' capability in shorter periods, such as might be used in EEO planning and labor negotiations. The data for these seniority level predictions are shown in Table 7. Again, the same relative predictive accuracy holds. The vacancy model is the best; the organizational Markov chain ranks second and the duration Markov chain is third. These findings hold for all three time periods and are viewed as significant in supporting the view that managerial choice and vacancy processes need to be accounted for in models of organizational labor mobility. Moveover, there is also indirect support for the incorporation of worker exit decisions which are conditional on managerial promotion decisions, since both models postulating such choice behavior outperformed the duration Markov chain model, which did not assume such processes.

5. FURTHER ANALYSIS OF THE VACANCY AND DECISION PROCESSES

In this section we further explore the relations between opportunities and individual behavior. This is especially important given the outcome of the comparative tests in which the OLD or demand model had the best predictive capability. We will take a fresh look at the data and focus on the two basic internal driving forces of the model: (1) managerial selection conditioned on opportunities and (2) vacancy flows across grades. For the selection process, we take the SGT grade as data[11] and for the vacancy flow processes, we use the entire ILM as data. These analyses are not to be construed as tests of the same kind as those in Section 4. Rather, they are intended to give further insight into the underlying processes which produced those results. Due to the small numbers at individual seniority levels, no discussion of statistical testing is considered in the analysis of managerial selection and opportunities; but, this by no means limits the importance of the inferential findings as to substantive significance. In the section on vacancy flows, there are two issues: the use of a model with a chain reaction effect to depict the underlying process generating individual mobility and the sources of the demand model's predictive errors.

Table 7. Average Yearly Relative Error[a] Over Time for Seniority Level Predictions

Time	Model	Grade COL	LT	SGT	CPL	TPR	All Grades[b]
1961–63	OMC	.25	.62	.21	.19	.07	.27
	DMC	.30	.74	.27	.21	.06	.32
	OLD	.20	.47	.20	.19	.06	.22
1961–65	OMC	.34	.86	.28	.26	.08	.36

[b] Equal weights per grade.

Managerial Selection and Opportunities

The demand model asserts that an individual's promotion chances over time are determined by managerial selection rules, the supply of individuals and their attribute profiles, and the number of promotion opportunities available. The number of opportunities fluctuates over time and we will look at years having few vacancies vs. years having more than a few vacancies entering the SGT grade. We refer to these selection years as "lean" and "fat" years, respectively. Within this dichotomy, we will examine the managerial selection processes for evidence of dependency on vacancy availability; that is, do the selection rules change as vacancies become fewer so that only "the cream of the crop" is selected, whereas, when more vacancies become available, a less discriminating selection process occurs? Since we are dealing only with selection by seniority, a thorough test of the stability of selection rules is not possible. Nevertheless, the seniority attribute per se provides interesting insights into the process. Lastly, we will look for evidence of cohort differences in terms of the degree to which they are "loaded with talent." Inferential evidence on this aspect may be obtained by looking at cohort promotion rates over the ten-year period, 1960–1969.

---

[11] Similar analyses may be conducted for other grades. The SGT grade, rather than the entire ILM, was chosen as a compromise between the need for adequately large populations and brevity.

Figure 7 provides the data necessary for these inquiries. The rows refer to seniority levels, the columns to years and the diagonal sets of entries to cohorts. A SGT cohort is defined as the group of persons entering the SGT grade at a specific year (analogous to a birth cohort in demography). The number of promotion opportunities or vacancies *entering* the SGT grade are given below each year at the bottom of the figure. The denominator in each cell is the number of persons originating in that state for that year. The numerator is the number of persons promoted to LT.

We make a crude cut between "fat" and "lean" opportunity years as follows:

LEAN—2-3 vacancies (1961, 1962, 1963, 1964, 1968),

FAT—5-11 vacancies (1960, 1965, 1966, 1967, 1969).

If we take the proportion of persons selected for promotion by seniority level for the FAT and LEAN periods, the selection parameters $\lambda_{LT,SGT}(s,t)$ are:

	S1	S2	S3	S4	S5	S6	S7	S8+	(N)
LEAN:	0	0	.08	.08	.15	.23	.31	.15	(13)
FAT:	0	.10	.05	.28	.13	.23	.05	.18	(40)

It appears that the selection probabilities change in response to opportunities. As opportunities expand (fat years), a much greater proportion of selections is made from lower seniority levels than when promotions are tight. In the lower four seniority levels, this ratio is 16% in lean years to 43% in fat years. Looked at from yet another perspective, in FAT years, 85% of selections are from S4–S8+; in LEAN years 84% are from S5–S8+; thus, the selection band decreases in LEAN years.

Evidence of cohort variation exists if we look at the diagonal cells. To view a cohort's behavior over time, take the 1960 cohort (S1, 1960) as an example. In each of the first four years none of the 15 persons was promoted. In the fifth year (S5), which was 1964, one person was promoted; in the sixth year, six were promoted (and one left—inferred from 7 in the denominator in seventh year) and in the seventh year no one was promoted from the seven persons remaining. The last year, S8+ has a mixture of cohorts—1960 and before—and, thus, has an asterisk on the denominator.

Consider the first seven cohorts (1960–1966) which have from 7 years (1960–1963 cohorts) to 4 years (1966 cohort) to be promoted from the S1–S7 levels. All have 3–4 fat years. The cumulative promotion ratio is as follows:

Seniority Level	S1,1960	S1,1961	S1,1962	S1,1963	S1,1964	S1,1965	S1,1966	S1,1967	S1,1968	S1,1969
S1	0/15	0/19	0/10	0/17	0/14	0/12	0/30	0/36	0/28	0/23
S2	0/8	0/15	0/19	0/10	0/17	0/14	0/12	4/30	0/36	0/28
S3	1/23	0/8	0/15	0/19	0/10	0/17	0/13	0/11	1/25	1/34
S4	3/21	0/22	0/8	0/15	1/19	1/9	3/16	1/12	0/11	3/23
S5	0/15	1/15	0/22	0/7	1/15	3/18	0/7	0/11	0/11	2/10
S6	0/9	0/15	1/13	1/20	1/6	6/14	1/11	1/6	0/11	1/10
S7	0/1	1/9	1/15	2/12	0/18	0/5	0/7	2/9	0/4	0/11
S8+	1/14*	0/7*	0/12*	0/18*	0/22*	1/33*	3/23*	1/13*	2/11*	1/8*
Year	1960	1961	1962	1963	1964	1965	1966	1967	1968	1969
No. Vacancies	(5)	(2)	(2)	(3)	(3)	(11)	(7)	(9)	(3)	(8)

Figure 7. Promotion Ratios by Seniority Level, Year, and Cohort for the SGT Grade: 1960–69

	Cohort						
	1960	1961	1962	1963	1964	1965	1966
% Promoted	.47	.37	.2	.18	.14	.17	.27
Cohort Size	15	19	10	17	14	12	30

The first four cohorts all have 7 years and show considerable variation in percentage promoted. This suggests that the distribution of talent, as measured by the selection criteria of the managers, differs by cohort. In fact, the 1966 cohort, which had but 4 chances (years), had a higher selection ratio than any cohort since 1961. These cohort data indicate, as we expected, that a much wider range of heterogeneity is operative than seniority can capture.

The two findings—cohort effects and variable selection rules—suggest that a much more complex selection process is operative. From the cohort data, we infer that multiple attributes of individuals must be considered. From the selection data, we add that one of these attributes must be seniority. A much larger issue is whether or not there are both multiple attribute heterogeneity and changing selection rules. To address this issue, much more detailed data on individual attributes are necessary. Moreover, the partitioning strategy used here (seniority levels within grade) will not be a feasible approach and some form of multivariate model for selection, such as a regression model, becomes necessary. Ginsberg (1972), Spilerman (1972), Wise (1975), and Tuma (1976) have all formulated regression models to generate the transition parameters of a PUSH or supply type of process for Markovian or semi-Markovian models. However, these approaches do not solve the problem where selection of individuals is CONDITIONAL ON OPPORTUNITIES: that is in a PULL or demand type of process.[12]

Vacancy Processes and Promotions

Lastly, we examine the mechanics of staff flows as depicted by the OLD model. First, we recast the observed flow data by using the OLD model to interpret theoretically the underlying vacancy processes which generate individual promotions. Second, we examine the sources of the OLD model's prediction errors.

The observed flow data are shown in Figure 8a. The solid lines denote person flows and the dotted lines vacancy flows, in this case the *net* number of new jobs (new jobs−jobs abolished). For instance, at the COL grade there are 29 exits, 4 new jobs (net) and 33 promotions into the grade from LT. Figure 8b takes these flow data and reinterprets them as a vacancy-driven process, having a chain reaction effect. Hence, the 33 promotions from LT open 33 vacancies which are added to the 20 vacancies arising there from exits and new jobs. This generates 53 vacancies which are filled by promotions from SGT, and so on. Thus, from the right side of Figure 8b, we observe a total of 475 vacancies entering (33 + 20 + 160 + 262) the ILM and generating a total of 774 promotions.

Had the parameters estimated from the 1950–1959 period been totally accurate, the model's predictions for 1960–1969 would have perfectly matched the flows in Figure 8b. Instead, we may observe where the model's parameters went wrong by viewing Figure 8c. Hence, the observed data, when theoretically interpreted as in 8b, act as a base line with which to investigate the source and magnitude of the OLD model's prediction errors.

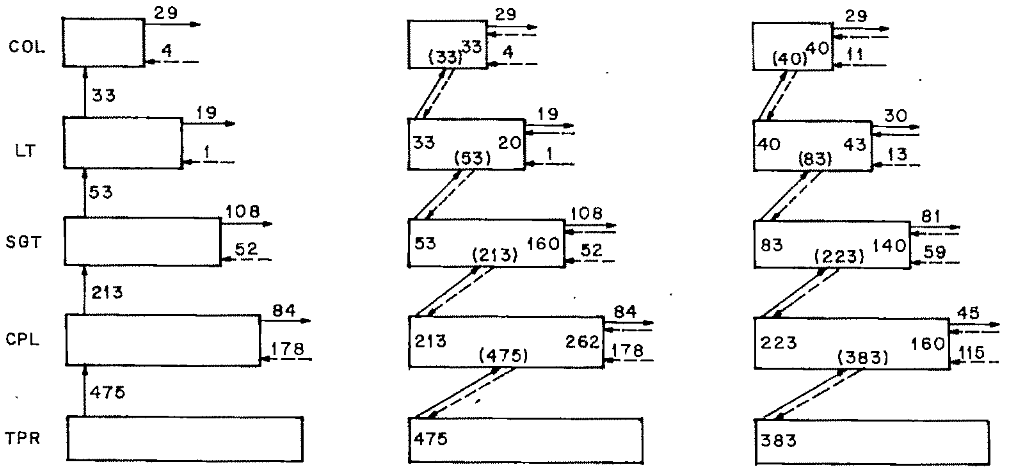
The two types of parameters causing prediction errors for promotions are exits and net new jobs. Looking at Figure 8b and c we find the data on predicted and observed exit rates are as follows:

	COL	LT	SGT	CPL
Predicted Exits	29	30	81	45
Observed Exits	29	19	108	84
Error	0	+11	−27	−39

The COL grade has no error, whereas the LT grade is overpredicted and the SGT and CPL grades underpredicted. In three of the 10 years, there were also un-

---

[12] In a sequel paper, one type of multivariate conditional selection model has been developed by the authors. The strategy assumes constant selection rules, as assumed in this paper, but specifies a ranking of individuals for selection. Thus, managers select the number of individuals from this ranking to fill available vacancies. And since vacancies fluctuate over time, an individual's promotion chances respond to *both* attribute profiles and available vacancies as they change over time.



8a. 1960–69 Observed Data

8b. OLD Model's Imagery of 1960–69 Observed Data

8c. OLD Model's Imagery Using 1960–69 Predictions

Figure 8. 1960–69 ILM Flow Data

derpredictions of exits at TPR, possibly suggesting the need for the incorporation of other individual attributes—in particular, age.

Data on predicted and observed *net* new jobs allocated per grade for this 10-year period may also be seen in Figures 8b and c. They are:

	COL	LT	SGT	CPL
Predicted net new jobs	11	13	59	115
Observed net new jobs	4	1	52	178
Error	+7	+12	+7	−63

We observe that all 7 promotion errors (40–33) to COL are accounted for by the error in new job allocations, as well as about half of the overestimates at LT. New job allocation errors at the SGT grade are small. The largest errors clearly arise in the CPL grade with underestimates of both new jobs and exits. The basis for new job allocation errors may be observed by comparing the predicted and observed relative grade distributions after the 10-year forecast:

	COL	LT	SGT	CPL	TPR
Predicted (1970)	.0192	.0220	.0989	.1940	.6659
Observed (1970)	.0134	.0129	.0923	.2284	.6530

The predicted values for 1970 are assumed to have the same distribution as in the estimation period, 1950–1959. The mechanism for obtaining this constancy is via $\hat{\rho}$, the parameter for allocation of new jobs, Equation 8. Compared with the observed distribution, we generally find economies of scale in the administrative ratio.[13] Economies of scale occur at COL, LT and SGT grades, but not at CPL, which results in the overpredictions of new jobs in the upper three grades and an underprediction at the CPL grade. Blau's (1970; 1972) organizational analyses suggest decreasing economies of scale as the work force being managed becomes more professional and Meyer (1972) adds to this discussion a component of technology—automation. He finds economies of scale at the first-line supervision of data-processing staff, but more vertical differentiation and less economy of scale for intermediate level management. Our case is the opposite of that found by Meyer; we find economies of scale at intermediate and higher levels of management. The most likely rationale for this unexpected divergence is the sudden shift from a 48- to 40-hour work week in 1966–1967. A historical analysis (Stewman, 1977) suggested labor input should be measured in terms of man-hours as well as number of workers. Thus, a decline in hours per worker would necessitate a corresponding managerial increase at some level, the most probable being the lowest administrative level. Hence, the underestimates of both exits and new jobs at CPL account for almost all of the TPR → CPL promotion errors, with the chain reaction component (223) very close to that which is observed (213).

---

[13] An economy of scale effect, in the context of an organization, is said to operate if a fractional increase in the size of the lower grade(s) requires a less than proportional increase in the size of the higher (administrative) grades. Correspondingly, if the proportional increase in the size of the higher grade were larger, then dis-economies or decreasing economies of scale are in effect.

6. CONCLUSIONS

This has been a first step in comparative analysis of models of organization ILMs with heterogeneous populations. We have comparatively tested two Markovian models of labor supply and a vacancy driven model of labor demand. The demand model's predictive capability was consistently better than either Markovian model. This finding is also consistent with prior ILM tests for homogeneous populations (Young and Vassiliou, 1974; Stewman, 1978). The results in this paper are viewed as particularly encouraging since the demand model made rather strong assumptions about how both vacancy and decision processes behave. In both types of processes, the assumptions are viewed as beginnings. An important step in the future will be to incorporate multivariate attributes of individuals in the selection and exit processes.

In view of these tests, the duration specific Markovian model seems most useful within organizational ILMs as a heuristic tool to summarize career segments. It is less useful as a predictive model than either the organizational Markov chain or the organizational labor demand model.

In summary, we have begun our analysis at the organization level—with internal labor markets defining the first structural effect. Secondly, we have considered an opportunity labor demand model which has secondary promotion impacts beyond those directly generated. (Thus, we treat second-degree structural effects.) Moreover, we have shown that this vacancy-driven model can predict person flows, which add further evidence to the predictive capabilities of vacancy type models in general. (White [1970], Stewman [1975b] and Brown [1975] had previously shown White's vacancy chain model to be a powerful model for predicting vacancy flows.) In brief, the vacancy type of model for person flows is not only more comprehensive theoretically than Markovian models, but it is also more accurate in predictions—long and short term.[14] Thirdly, we have postulated three types of decision-processes: allocation of new jobs, worker exits, and managerial selection. The importance of explicitly including decision processes is that we once again bring back individuals into models of organizational social structure. Moreover, these individuals are assumed to have minds and cognitive abilities to make choices, and, thus, in part at least, participate in actively structuring the basic processes themselves.

RESEARCH NOTES

TRUTH TESTS AND UTILITY TESTS: DECISION-MAKERS' FRAMES OF REFERENCE FOR SOCIAL SCIENCE RESEARCH*

CAROL H. WEISS
Harvard University

MICHAEL J. BUCUVALAS
Louis Harris and Associates, Inc.

American Sociological Review 1980, Vol. 45 (April):302–313

In an effort to contribute to an empirically based "sociology of knowledge application," this paper explores the frames of reference that decision-makers employ in assessing the usefulness of social science research for their work. Analysis of responses of 155 decision-makers in mental health fields to 50 actual research reports reveals five frames of reference: relevance of research topic, research quality, conformity of results with expectations, orientation to action, and challenge to existing policy. All frames are positively associated with perceived likelihood of using a study. Two significant interactions among the frames suggest that, in essence, decision-makers apply a "truth test" and a "utility test" in screening social science research. They judge truth on two bases: research quality and/or conformity with prior knowledge and expectations. They also assess utility on alternaive bases: feasible direction for action and/or challenge to current policy. The ways in which they apply research conclusions to their work is a broader, more diffuse, and wider-ranging process than many earlier investigators have recognized.

In 1949, Robert Merton called for systematic study of applied social science and of the factors that facilitated or impeded its utilization for purposes of practical action. His luminous analysis discussed the cultural, organizational, situational, and cognitive contexts of applied social research and pointed to the need for empirical investigation of their implications for research use. He identified such dimensions as the prevailing images of applied social science and the often divergent value frameworks of policy-maker and researcher as they affect "the relevance, scope and utility of the research itself" (Merton, 1949:173). In the ensuing years, much speculation (but little research) has followed the lines of Merton's prescriptions.

Recently Holzner has continued the discussion by suggesting the development of a "sociology of knowledge application," in effect a sociology of knowledge "turned upside down" (Holzner, 1978:8). Whereas the classical sociology of knowledge was concerned with the social basis of intellectual productions, a sociology of knowledge application would be concerned with the social consequences of knowledge. In particular, it would investigate the conditions under which knowledge is produced, diffused, and applied. Where Merton called for an applied social science of applied social science, Holzner is, in effect, pointing the way toward a basic social science of applied social science. He, too, calls attention to the need for understanding the multiple frames of reference with which actors perceive knowledge and the discrepancies between the frames of reference of knowledge producers and knowledge users.

This paper reports empirical evidence on decision-makers' frames of reference for social science research. Frames of reference, as we use the term, refers to the dimensions of research that are salient to persons in assessing a study, in effect their criteria for accepting or rejecting the results of the research. Based on interviews with 155 officials in upper-level positions

This study was conducted at Columbia University under a grant from the National Institute of Mental Health.

in federal, state, and local agencies in the fields of mental health, alcoholism, and drug abuse,[1] our data come from their responses to 50 actual research reports.[2] Each person read two of the 50 research reports, which we had summarized in standard-format two-page abstracts.[3] They then rated each one on 29 descriptive dimensions, including such items as technical quality, objectivity, applicability of findings within existing programs, congruence with potential users' ideas and values, and political acceptability of the findings.[4] From their ratings of concrete studies, we derived their frames of reference.

Frames of Reference

The analytic strategy for identifying frames of reference was factor analysis. In this case, factor analysis of respondents' ratings was more than a data reduction technique. It was an effort to locate the constellations of study characteristics that formed analytically separable dimensions. It was, in effect, a means to define the constructs that respondents use to describe and assess research. Table 1 shows the five factors that emerged from the analysis.[5]

The first factor, Research Quality, contains a cluster of items related to the scientific merit of the research: technical quality, statistical sophistication, objectivity, quantitative data, internal consistency, data support for recommendations, comprehensive set of explanatory variables, generalizability, validity, addition to descriptive or causal knowledge. This factor captures the basic components of research merit. It includes methodological

---

[1] We interviewed 51 federal, 52 state, and 52 local officials. Respondents at the federal level held positions at bureau chief level or above in the National Institute of Mental Health (NIMH), the National Institute of Drug Abuse (NIDA), the National Institute of Alcohol Abuse and Alcoholism (NIAAA), and their parent body, the Alcohol, Drug Abuse, and Mental Health Administration. State officials served in the tier of positions immediately below the commissioner or director of mental health in ten states, with titles such as deputy director, director of community programs, director of psychiatric facilities, director of addiction services. Local officials were directors of mental hospitals, mental health centers and clinics, or chiefs of service within those facilities. Also interviewed were 50 social scientists who did research under funding from NIMH, NIDA, and NIAAA and 50 members of research review committees in the same Institutes, but we do not discuss those data here.

[2] The reports that we presented to respondents during the interview were drawn from reports of recently completed social science research studies sponsored by NIMH, NIDA, and NIAAA that evidenced a modicum of technical competence. We selected them to be representative of the spectrum of both grant and contract research, with purposive variation on three dimensions: manipulability of major independent variables, administrative implementability of study's conclusions, and political acceptability of the study's findings in light of current policy. A major selection concern was to uncouple these three characteristics; so we developed a matrix representing the eight possible combinations and selected studies to fill all cells of the matrix. We also tried to vary such other dimensions as type of study, type and size of sample, and substantive focus.

[3] The abstracts included sections on: objectives of the study, methods (site, sample, variables investigated, how variables were operationalized, methods of data collection and analysis), major findings, conclusions, and (if relevant) recommendations.

[4] The descriptors were intended to be a comprehensive list of research characteristics, with particular emphasis on those which observers have claimed affect the use of research. The list was developed after extensive review of the literature and considerable pretesting. Twenty-six of the items are listed in Table 1; the other three are described in fn. 5. Respondents rated the extent to which each descriptor applied to the study on a 5-point scale, from "to a great extent" to "not at all."

[5] The factor solution presented is based on 510 ratings by 255 interview respondents, including social science researchers and research review committee members, because we want a solution that can be used in other analyses for comparisons across groups. The solution for decision-makers alone is not materially different. Four of the descriptors that were rated are excluded from the factor solution. "Inexpensive to implement" was not rated by 35% of the respondents; when the item is included in the factor analysis, it forms a separate factor. "On time for a pending decision" and "deals with a high priority issue" load on a fifth factor with the item, "relevant to the issues your office deals with," which was asked only of decision-makers. This factor, which we call Relevance, is not included here because the key item was rated only by decision-makers and "on time for a pending decision" has missing observations in 41% of the cases. For analysis of decision-makers' responses, we use the single item, "relevant to the issues your office deals with" as the indicator of Relevance. The solution presented is the result of an oblique rotation using a direct oblimin criterion. The four unrotated factors were the principal components with eigenvalues greater than 1.0 from a matrix of Pearson correlation coefficients with missing observations deleted pairwise.

Table 1. Factors of Research Characteristics

Loading[a]	Factor I (Research Quality)
.922	Technical quality of the research is high
.890	Statistically sophisticated
.794	Objective, unbiased
.745	Provides quantitative data
.702	Findings are internally consistent and unambiguous
.634	Recommendations are supported by the data
.625	Comprehensive—that is, includes most of the potentially explanatory variables in analysis
.612	Generalizable to equivalent populations
.569	Validity of findings
.560	Adds to descriptive, causal, theoretical knowledge
	Factor II (Action Orientation)
.706	Contains explicit recommendations
.703	Analyzes effects of factors that decision-makers can do something about
.664	Targeted—that is, focuses on a narrow set of dependent, or outcome, variables
.661	Has direct implications for a course of action
.605	Findings can be applied within existing agencies and programs
.526	Adds to practical knowledge about the operation of policies or programs
	Factor III (Conformity to User Expectations)
.745	Supports a position already held by the user
.718	Consistent with a body of previous knowledge
.663	Compatible with the ideas and values of the potential user
.613	Agrees with respondent's sense of the situation
−.550	Findings unexpected or novel (negative)
	Factor IV (Challenge to Status Quo)
.764	Challenges existing assumptions and institutional arrangements
.738	Implies the need for major change in philosophy, organization, or services
.574	Raises new issues or offers new perspectives
−.437	Implications of the findings are politically acceptable (negative)

[a] The loadings are from the factor pattern matrix after oblique rotation. All loadings over .40 are shown.

and normative items, items related to internal and external validity, and items suggesting appropriate theoretical grounding (for example, "comprehensive set of explanatory variables") as well as appropriate methods.

The second factor deals with the practicality of implementing the findings. Labeled Action Orientation, it contains the items on practical problem-solving: explicit recommendations, manipulable variables, targeted set of dependent variables, direct implications for a course of action, applicability within existing programs, and addition to *practical* knowledge. This is the frame of reference widely attributed to clients of applied research. It tells them what to do on things that they can do—within existing constraints.

Conformity to User Expectations, the third factor, represents compatibility with what users know and believe. As social scientists have long suggested, decision-makers view research through the lens of their previous beliefs. The items in this factor include: support for users' position, consistency with previous knowledge, compatibility with users' ideas and values, agreement with the users' sense of the situation, and findings *not* unexpected or novel. Thus, the Conformity frame of reference contains the notion of congruence with users' values and policy positions, but even more pervasive is the sense of conformity with what they already know—or believe they know. Four of the five descriptors that comprise the factor refer to users' knowledge, ideas, sense of the situation, and expectations. The emphasis is on agreement with the users' construction of reality. Furthermore, it is agreement with the users as individuals rather than as organizational members. Items relating to organizational practice and political context load on the next factor.

We call the fourth factor Challenge to the Status Quo. It relates primarily to the operation of institutions rather than to the preferences of individual users, and its thrust is major disagreement with institutional practice. Included in this factor are:

challenge to assumptions and institutional arrangements; implications for major change in philosophy, organization, or services; new issues or new perspectives; and politically *un*acceptable implications.

A fifth frame of reference has to do with the Relevance of a research study to the users' work. Timeliness of the research and high priority of the issue loaded on the same factor as the key item, "relevant to the issue your office deals with," but because of rating procedures and missing observations, we (see fn. 5) use the single item on relevance as the indicator. Clearly, the substantive fit of a study to the users' job responsibilities is a criterion to which people are alert in assessing research. The procedures of our study aimed to ensure relevance by matching studies to respondents' job titles insofar as possible, but enough variability remained so that Relevance emerges as a dimension to which they respond.

The major surprise to us in these data is respondents' separation of their own beliefs from the beliefs and arrangements underlying institutional practice. Conformity to User Expectations and Challenge to the Status Quo are separate dimensions, not opposite ends of a continuum. In our data, they are not negatively correlated; they are essentially not correlated at all (r = .05). The pattern of data suggests that people in positions of organizational authority are about equally likely to agree—as they are to disagree—with findings that challenge institutional policy and practice. Although the items referred to mental health arrangements and practice, generally, rather than to the practices of the particular agencies with which each respondent was connected, there is little support here for the prevalent assumption that bureaucrats are firmly committed to institutional policy.

Relationship of Frames of Reference to Usefulness

Having located five frames of reference, the next step was to see what effect each factor had on the perceived usefulness of research. One measure of usefulness was the question, "Assuming your office had to consider the issues discussed in the study, how likely is it that you would take the study results into account?" Respondents rated each study on a 5-point scale (analogous to the 5-point ratings on the descriptor items) from "very likely" to "not likely at all."

It can be argued that the perceived usefulness of social science research is a soft indicator and that actual use would be more appropriate. However, one of the most powerful learnings from the first round of empirical investigation of research utilization (for example, Caplan et al., 1975; Caplan and Barton, 1976; Rich, 1975; Patton et al., 1977) is that "use" is an exceedingly ambiguous concept. Officials interpret using research to mean anything from adoption of the recommendations of a single study all the way to a general sensitivity to social science perspectives (cf. Caplan et al., 1975:18–19). And not only are interpretations of use highly variable, but also the *phenomenon* of use is an amalgam of diverse activities. People can use social science research to clarify the relative advantages of alternative choices, but they also use it conceptually: to understand the background and context of program operation, stimulate review of policy, focus attention on neglected issues, provide new understanding of the causes of social problems, clarify their own thinking, reorder priorities, make sense of what they have been doing, offer ideas for future directions, reduce uncertainties, create new uncertainties and provoke rethinking of taken-for-granted assumptions, justify actions, support positions, persuade others, and provide a sense of how the world works. Pelz (1978:347) has summarized the diverse uses of research in three categories: instrumental/engineering, conceptual/enlightenment, and symbolic/legitimative. (See also Rein, 1976; Gans, 1971; Coleman, 1972; Lazarsfeld and Reitz, 1975; Lindblom and Cohen, 1979; Straussman, 1978; Aaron, 1978; Cohen and Garet, 1975; Cherns, 1976; Cherns et al., 1972; Weiss, 1979; 1980; Frankel, 1976). We want to capture the array of uses of social science research, partly because direct and immediate applications of research to decisions are rare—given the nature of organizational decision-making processes;

more importantly, direct applications are one extreme of a continuum that gradually shades into uses that are less immediately obvious but, nonetheless, real—and potentially powerful in cumulative consequence.

Before any kind of use can occur, officials have to consider a study worth their attention and give it a hearing. Their determination that a study deserves notice and should be taken into account in their work is what our measure taps. Much information comes and goes without a trace, but a study that is deemed worthy of serious attention deposits a residue of information and ideas that can be retrieved when circumstances are conducive to use.

We regressed the usefulness ratings on the four factors and Relevance. Table 2 presents the standardized regression coefficients. All of the factors are positively associated with the usefulness of research studies, and all of them are significant predictors. Together they account for 42% of the variance in the likelihood of using a research study. Characteristics of studies make a sizable difference in their usefulness.

In light of much of the previous literature on research use, two of the coefficients are unexpected. First is the salience of Research Quality, which has the highest coefficient in the equation. The weight of opinion among social scientists (including those whom we interviewed in this inquiry) is that decision-makers are unconcerned about scientific quality: if a study supports what they want to do, they accept and use it, but if it does not, they reject it (Horowitz, 1970; Komarovsky, 1975; Wilson, 1978). One possible explanation for the unexpected showing is that respondents are overstating their allegiance to Research Quality in the interests of social acceptability. However, the questions in the interview did not ask them directly about the factors that affected their likelihood of using a study. Rather, each person rated the usefulness of the study, answered a set of open-ended questions, and then rated the study on the descriptors. Our analysis is based on the statistical relationships between the ratings of the descriptors and of usefulness.

Another set of evidence suggests that lying is not the explanation. Early in the interview, we asked respondents' *opinions* about the characteristics of research studies that would affect their use. Here, if anywhere, social desirability biases should surface. On this question, some of the items that were part of the Research Quality factor received high ratings but others did not, and comparison (between the opinion ratings and the effects of the same items on the usefulness ratings) indicated little correspondence. The items that a person *believed* were important for use did not match the items that were associated with that person's own ratings of the usefulness of a study. This datum makes the notion of purposeful misreporting less persuasive.

On the other hand, in the interview a person may have tended to inflate the Research Quality ratings of the studies he/she found useful. Such a tendency may have elevated the relationship between Research Quality and likelihood of use. However, her/his ratings of Quality correlated significantly, study by study, with the ratings given by social science researchers and members of research review committees. And even if we allow for some possible ambiguity in the causal

Table 2. Regression of Ratings of Likelihood of Use on Research Characteristics

Independent Variables	Unstandardized Regression Coefficient	Standard Error	Standardized Regression Coefficient
Relevance	.14	.05	.15
Research Quality	.54	.08	.39
Conformity to User Expectations	.25	.07	.18
Action Orientation	.16	.08	.12
Challenge to the Status Quo	.26	.08	.19
Constant	3.34		
$R^2 = .42$.			

relationship, the strong association between Research Quality and usefulness remains noteworthy.

There are good reasons for consideration of a study's Research Quality within the environment of an operating agency. When officials rely on social science research as a source of information, rather than such available alternatives as impressionistic accounts, program records, or the agency grapevine, the rationale is that research provides more valid information. The claim to validity is based on adherence to the canons of science and, unless the canons are obeyed, research is expensive and troublesome, with no gain in accuracy. Furthermore, agency actions can have large consequences—in terms of dollars and human lives. If officials are to take research seriously, they want to have confidence that the evidence they consider is trustworthy.

Other data in the interview show that there are political reasons for insisting on Research Quality. One question asked how appropriate each study report would be for seven listed functions, such as raising an issue to attention, and formulating new policies and programs. Analysis showed that Research Quality was a particularly important feature of studies that were appropriate for two purposes: mobilizing support for a position or point of view, and changing ways of thinking about an issue. The suggestion is that Research Quality is particularly valued for studies that enter the arena of debate. If officials rely on research in the adversarial process of decision-making, they want the study to provide effective ammunition. If it can be discredited on methodological grounds, they are left out on a limb. Research Quality, thus, not only assures decision-makers that they are basing a case on good evidence but also serves the political function of protecting the case from methodologically based criticism.

The second surprise in Table 2 is the positive and significant regression coefficient for Challenge to the Status Quo. One would think that a study that challenges existing practice, implies the need for fundamental change, and is politically unacceptable would hardly seem useful. But mental health decision-makers rate studies that score high on Challenge as particularly likely to be taken into account.

Three explanations are suggested by the data. First, recall that respondents' ratings of the research studies indicate low levels of allegiance to existing practice. The correlation between the factor scores for Challenge to the Status Quo and Conformity to User Expectations is essentially nil. Therefore, studies that challenge current practice are as likely to accord with their beliefs as to contravene them. As one person noted, unless a mental health official is dissatisfied with today's programs and looks toward change, he/she forgoes a position of leadership in the field.

Second, usefulness is defined in the interview as the likelihood of taking the study into account in the work of one's office. This definition does not demand that respondents expect to implement the results or make a specific decision differently because of the results. They can take the research into account by considering its implications. This kind of research use lacks the crispness of the traditional formulation of "research utilization": using research as a basis for choosing between decision A and decision B. But elsewhere in the interview, they described their previous experiences in using research, and their descriptions show that they rarely rely on research to make such clear-cut decisional choices. Instead, the use of research in large organizations is primarily to provide background, understanding, awareness of new ideas. When they turn to research (and most of our respondents reported that they read research and believed it made a difference to their work), it is precisely for the seemingly diffuse purposes of enlightenment. Thus, the measure accords with the modes of use that are prevalent in these agencies (Caplan et al., 1975; Patton et al., 1977; Weiss, 1980; Alkin et al., 1979).

In this context, Challenge to the Status Quo is a positive feature of research. When research raises questions about current policy and suggests fundamental change, it helps people learn about problems and identify alternatives. Research that confirms that current policy is working well offers little food for thought. Research that challenges policy stimulates people to rethink their positions and to grapple with new opportunities. They find such research valuable.

A third reason for the strong showing of Challenge to the Status Quo may be that the research studies that we presented to respondents were drawn from the stock of recent federally supported social science research studies. They exhibited varying degrees of Challenge to the Status Quo, but none questioned fundamental assumptions of the economic or social order. As radical as they may have been on mental health policy issues at the time (for example, offering evidence to support community control of care-giving facilities), they did not suggest basic changes in societal institutions. We are dealing with Challenge within a limited range.

The other data in Table 2 are more expected. The Relevance of a study to a user's job responsibilities increases its likelihood of being taken into account. So does its Conformity to User Expectations, since research that is intuitively "right" and supportive of preconceptions is easier to accept. So, too, does Action Orientation, the set of characteristics that makes a study feasible to apply. That Action Orientation does not show a higher association with likelihood of use, as many social scientists would expect, is probably attributable to the same definitional premise that underlies the salience of Challenge. Because research studies are seldom used as a direct basis for decisions, Action Orientation turns out to be less important than is commonly asserted. But the practicality dimension embedded in this frame of reference retains a positive effect on usefulness.

Truth Tests and Utility Tests

From a sociology of knowledge perspective, we can see that decision-makers use two tests to screen incoming social science research: a truth test and a utility test. They are concerned with the validity of research results, and they are concerned with the direction that research provides for future action. In terms of validity, they have two bases on which to make their evaluation: the degree to which the research adheres to the canons of the scientific method (Research Quality) and the degree to which the findings of the research accord with their previous knowledge of how the world works (Conformity to User Expectations). Each component of the truth test represents an alternative mode for judging whether the results are accurate.

Scientists are accustomed to judging validity primarily on the basis of the research *process*—the degree to which appropriate theory and methods were used to arrive at conclusions. Decision-makers, in addition, judge validity by the *outcomes* of the research. They invoke a criterion derived from their direct involvement in the substantive area, and they assess the extent to which research outcomes agree with their firsthand experience and professional judgment. Because they are exposed to a variety of evidence—direct observation, descriptive accounts, program data, routine statistics, colleagues' reports, as well as a body of previous research—they use their stock of knowledge to help them judge the truth of a study. Of course, this kind of comparison is not unknown to scientists, who also have referents in an existing body of knowledge. The fact that decision-makers' prior knowledge is less formal and systematic does not diminish, but perhaps strengthens, its salience. It has the vividness of immediacy.

Thus, the truth test is composed of two independent dimensions. Decision-makers appraise a study in terms of its technical merit, but they have another basis for screening its truth claims—its conformity with their prior understanding and experience.

The utility test, too, is made up of two analytically distinct components. One is the extent to which a study provides explicit and practical direction on matters they can do something about—the constellation of characteristics we have called Action Orientation. This dimension captures the essence of the injunctions to applied social scientists that abounds in the "problem-solving" literature: be practical, accept decision-makers' parameters of action, analyze manipulable variables, draw explicit recommendations. It represents one of the grounds on which decision-makers test a study's utility.

But there is a different kind of guidance that social science research can provide, which has been called "enlightenment" (Crawford and Biderman, 1969; Janowitz, 1970). It encompasses a range of conceptual contributions, from helping to "establish new goals and bench marks of the attainable" (Merton, 1949:170), to helping to "enrich and deepen understanding of the complexity of problems and the unintended consequences of action" (Aaron, 1978:166), to guiding the "effort to interpret and structure the social world by establishing languages and symbolic universes used in comprehending and carrying on social life" (Cohen and Garet, 1975:42). Such conceptual uses suggest that there are alternatives to working within decision-makers' established constraints and to generating data to aid them in weighing the costs and benefits of available options. Research can be useful by challenging current practices and suggesting new perspectives and orientations. Our data show that decision-makers value research that scores high on Challenge to the Status Quo. They are receptive to findings about the ineffectiveness and dysfunctions of current policy as well as about its successes; they are open to new formulations and approaches, even when these are not yet politically acceptable.

Just as Research Quality and Conformity to User Expectations seem to be alternative ways of satisfying the truth test, so Action Orientation and Challenge to the Status Quo appear to be alternative grounds for satisfying the utility test. The next section analyzes the extent to which each test is in fact an entity.

Components of the Truth and Utility Tests

The components of Research Quality and Conformity to User Expectations constitute a unitary truth test if the level of one factor is contingent on the level of the other. Our hypothesis is that the more closely research results fit with what users already know (Conform to their Expectations), the less important will Research Quality be for their likelihood of taking the study into account. Conversely, when a study's conclusions diverge from the "known," the more important is its Research Quality for overcoming their doubts and motivating them to take it seriously. Similarly, we hypothesize that Action Orientation and Challenge to the Status Quo comprise a utility test because they provide *alternative* types of direction. If a study scores high on one component, it is less important to the study's usefulness that it score high on the other. Although the hypotheses are different in substance, they can both be represented by negative interactions between the factors.

Accordingly, we constructed product terms for the interaction of Research Quality and Conformity and for the interaction of Action Orientation and Challenge to the Status Quo, and added the two terms to the regression equation presented in Table 2 (Cohen and Cohen, 1975:chap. 8). Table 3 presents the unstandardized regression coefficients[6] from the regression of likelihood of use on Relevance, the four factors, and the two interactions.

Both hypothesized interactions are negative, substantial, and statistically significant ($p < .01$). Together they add 3% to the variance explained, an amount significant at $p < .01$. None of the other possible two-way interactions (not presented) is of comparable magnitude or statistically significant at the .05 level.

We hypothesized that the effects of Research Quality on usefulness are contingent on Conformity to User Expectations, rather than vice versa, because

---

[6] When there are no interactions, unstandardized coefficients are effect, or slope, coefficients; they indicate how much change will occur in the predicted value of the dependent variable for a one-unit change in any particular independent variable. When there are interaction terms, the situation is more complex. Slopes are rates of change and mathematically are equivalent to first partial derivatives. If we want to compute the slope of the regression surface for any independent variable, we must take the first partial derivative of the regression equation for that particular variable.

Table 3. Regression of Ratings of Likelihood of Use on Research Characteristics and Hypothesized Interactions

Independent Variables	Unstandardized Regression Coefficient	Standard Error	Standardized Regression Coefficient
Relevance	.13	.05	.14
Research Quality	.55	.07	.39
Conformity to User Expectations	.26	.07	.19
Action Orientation	.13	.07	.10
Challenge to the Status Quo	.28	.07	.20
Quality × Conformity	−.20	.07	−.12
Action Orientation × Challenge	−.19	.07	−.12
Constant	3.14		
$R^2 = .45$.			

decision-makers' knowledge and beliefs antedate their review of the study, and their judgments of its truth depend on their stock of knowledge. The interaction term itself is symmetric and does not indicate which effect is contingent. We impose the limiting concept. What the interaction term tells is the magnitude of change in the effects of Research Quality.

By calculating the first partial derivative of the regression equation for Research Quality, we see that the effect of Research Quality on likelihood of use is .55−(.20 × Conformity). When the value of Conformity is 0 (its mean), the slope of Quality is .55. For each unit increase in Conformity, the effect of Quality is attenuated by .20, so that studies with Conformity scores of +1.0 would show increases of .35 in likelihood of use for each unit increase in Quality. For each unit decrease in Conformity, the effect of Quality is enhanced by .20; studies with Conformity scores of −1.0 would show increases of .75 in likelihood of use for each unit increase in Quality. Thus, Research Quality has more than twice as large an effect when Conformity is −1.0 as it has when Conformity is +1.0. If a study yields counterintuitive findings, Research Quality is much more important than it is when findings are compatible with users' preexisting ideas.

The pattern of data raises the possibility that if Conformity were high enough, the effect of Quality would be negative. This does not happen within the existing range of data. Conformity scores go from −2.98 to +2.04, so that, at the highest end, Research Quality is still positive (.14). Our guess, based on the conceptualization of the truth test, is that increased Quality would never decrease usefulness, other factors being controlled. At worst, the effect of Quality might be nil, but it is clearly most significant when findings do not accord with users' beliefs.

In the utility test, where the two component factors represent alternative modes of providing direction, both the interaction term and the conceptualization are symmetric. Therefore, we compute both slopes. For Action Orientation, the slope is .13−(.19 × Challenge to the Status Quo). For Challenge, the slope is .28−(.19 × Action Orientation).

For the slopes of both components, the attenuation coefficient of the other component is relatively large, compared with the constant. Both factors have negative effects on likelihood of use within the existing range of data. For Action Orientation, the slope becomes negative for all values of Challenge of .68 or above; this represents almost one-quarter of the cases. For Challenge, the effects become negative when Action Orientation takes on values over 1.47 (about 5% of the cases). When both components are high, the study scores lower on likelihood of use than a simple additive combination would predict.

In fact, the size of the coefficient of the interaction term relative to the coefficients of the first-order terms suggests that in cases where both factors were high enough, an increment in either of them would actually decrease the study's likelihood of use. No such cases occur in our data set; there are cases where one of the components enters the required range, but in these cases the other does not.

Highly Challenging research that is also high on Action Orientation is probably rare. If it did occur, the negative interaction suggests that it would actually decline in usefulness.

The "trade-off" effect demonstrates that the two bases of utility are alternatives to each other. Action Orientation is much more important when a study does not Challenge the Status Quo, and Challenging results are more useful when a study is not Action-Oriented. When a study's results are feasible to implement, evidence of major deficiencies in practice or fundamentally new perspectives do not add much to its usefulness. When a study suggests radical redirection of policy or program, explicit direction for implementation adds relatively little to usefulness; respondents are receptive to its ideas, but they are not prepared to take immediate steps to carry out its recommendations.

Conclusion

Decision-makers in federal, state, and local mental health agencies are exposed to reports of large numbers of social science research studies—in books, journals, professional magazines, and the mass media; in reports from agencies' contract and grant awards, routed from other divisions and mailed in by researchers; through conferences, meetings, and colleagues' discussions. Their professional backgrounds (largely in psychiatry, psychology, and social work) attune them to research procedures, and they are generally receptive to the contributions that the social sciences can make to policy and practice.[7] In coping with the incoming flood of information, they invoke three basic frames of reference. One is the relevance of the content of the study to their sphere of responsibility, another is the trustworthiness of the study, and the third is the direction that it provides. The latter two frames, which we have called truth and utility tests, are each composed of two interdependent components: *Truth test:* Is the research trustworthy? Can I rely on it? Will it hold up under attack?

1. Research Quality. Was the research conducted by proper scientific methods?

and/or

2. Conformity to User Expectations. Are the results compatible with my experience, knowledge, and values?

Utility test: Does the research provide direction? Does it yield guidance—either for immediate action or for considering alternative approaches to problems?

1. Action Orientation. Does the research show how to make feasible changes in things that can feasibly be changed?

and/or

2. Challenge to the Status Quo. Does the research challenge current philosophy, program, or practice? Does it offer new perspectives?

Together with Relevance (that is, the match between the topic of the research and the person's job responsibilities), these four dimensions constitute the frames of reference by which decision-makers assess social science research. Research Quality and Conformity to User Expectations form a single truth test in that their effects are contingent on each other: Research Quality is less important for the usefulness of a study when results are congruent with officials' prior knowledge than when results are unexpected or counterintuitive. Action Orientation and Challenge to the Status Quo represent alternative functions that a study can serve. They comprise a utility test, since the kind of explicit and practical direction captured by the Action Orientation frame is more important for a study's usefulness when the study provides little criticism or reorientation (Challenge to the Status Quo) than it is when Challenge is high. Conversely, the criticism of programs and new perspectives embedded in Challenge to the Status Quo add more to usefulness when a study ignores feasible prescriptions for implementation.

It is worth emphasizing that decision-makers are receptive to studies that are high on Challenge to the Status Quo, with its connotation of fundamental reorientation in policy assumptions and practice. They want to hear reports critical of current programming and they are willing to take account of variant perspectives. Given the emphasis in much previous work on bureaucratic inertia and resistance to change, this openness in mental health agencies strikes an optimistic note—even though their attention to such research provides no guarantees that it will affect immediate decisions in direct and discernible ways.

---

[7] Caplan et al. (1975), who interviewed high officials with much more diversified backgrounds across a wide range of federal departments, found equally receptive attitudes toward social science research.

Finally, it is important to note that "using research" is a much broader and more diffuse concept here than the research-for-problem-solving literature adopts. Our formulation, "taking research into account in the work of one's office," does not restrict use to direct effect on decisions. It allows for the multiple functions that research can serve—generating awareness of needs, problems, and shortcomings in service; providing news about strategies that are proving effective; alerting people to environmental changes and emerging issues; reducing the uncertainties that inevitably attend complex issues; justifying current policies; offering ideas and concepts for making sense of experience; constituting a language for communication with other actors in the public arena. Other data in the study confirm that officials "use" research in this variety of ways (Weiss, 1980) and that research can be "useful" to them on many bases. Our understanding of research utilization has to go beyond the explicit adoption of research conclusions in discrete decisions to encompass the assimilation of social science information, generalizations, and ideas into agency perspectives as a basis for making sense of problems and pondering strategies of action.

THE SPATIAL STRUCTURE OF INCOME DISTRIBUTION IN RURAL REGIONS*

DAVID A. MCGRANAHAN
University of Wisconsin

American Sociological Review 1980, Vol. 45 (April):313–324

Drawing on the concepts of metropolitan spread and central place hierarchy, this paper develops a spatial model of income distribution in rural regions. Central to the model is the argument that proximity to growing metropolitan centers and community commercial centrality affect incomes differentially, in ways that depend on education, age, and proprietorship. It is argued that these differential effects are reflected in the distribution of income across and within communities, having implications for community stratification, structure, and, following Molotch (1976), the differentiation of interests in community growth.

INTRODUCTION

An important thesis in current stratification research is that the labor market is segmented, that the effects on income of education, experience, and other individual attributes are not uniform but depend on position in the socioeconomic structure—namely, on class position (Wright and Perrone, 1977); on the central or peripheral nature of the industry (Bibb and Form, 1977; Beck et al., 1978); and on the size of the employing organization (Stolzenberg, 1978). Are there also aspects of spatial structure which affect relationships between individual characteristics and income, or is the distribution of income across and within communities and areas simply a reflection of the spatial division of labor, with migration serving to integrate the structure of opportunities?

This question has received little theoretical or empirical attention and the evidence is unclear. Income levels depend on location as well as individual attributes (Duncan and Reiss, 1956; Hanushek, 1973; Parcel, 1979), but this could simply reflect areal differences in the cost of living. Studies of relationships between indi-

Revised version of a paper presented at the annual meeting of the Midwest Sociological Society, 1979. Research supported by the National Institute of Mental Health (Grant No. ROL MH 25266–01, E. A. Wilkening, P. I.), and the Research Division of the College of Agricultural and Life Sciences, University of Wisconsin-Madison. I thank D. V. McGranahan, E. A. Wilkening, V. Lambert, D. Featherman, and J. G. Williamsen for commenting on earlier versions of this paper.

vidual characteristics and income status within communities indicate that there is little variation among the largest U.S. northern cities (Mueller, 1974), that there is no systematic variation by community size (Hochbaum et al., 1955; Lane, 1968; Hauser and Featherman, 1977; Curtis and Jackson, 1977), but that there may be differences among smaller communities (Curtis and Jackson, 1977). The more recent of these studies have generally concluded that communities do not have economic stratification systems which are separate from that of the larger society. Given that the annual intercounty migration rate is about 10% for people aged 20–44 (U.S. Department of Commerce, 1977), this conclusion would seem reasonable.

The question of how location and income are interrelated may be approached from a different perspective, however. For instance, migration is a highly selective process. Research has consistently shown that the propensity to migrate increases with education and decreases with age, until the age of retirement (Ritchey, 1976). The effects of location on income may be greater for those segments of the labor force with relatively little geographical mobility. Thus, instead of asking how relationships of individual characteristics to income may be influenced by community or area context, it may be useful to look at how the importance of location on income varies, depending on individual characteristics. This point is important because the above community studies are based on very small or pooled samples of communities,[1] selected or combined on the premise that communities or areas have contained stratification systems, with city size (rather than growth or decline, for instance) as the major contextual variable.

This paper develops a model of income distribution in rural regions, focusing on ways in which incomes may vary by location, depending on individual characteristics. In the first sections of the paper, the differential effects on incomes of metropolitan spread and community commercial centrality are discussed with reference to education, age, and proprietorship; and the implications of these differential effects for community income levels and inequality are examined. Education and age are key variables in stratification (and mobility) research. While the distinction between proprietary incomes and wage and salary incomes is usually treated only peripherally (but, see Wright and Perrone, 1977), it is especially important in rural regions where many of the businesses are individually or family owned. Evidence for the model is then presented, using individual and community level data from northwestern Wisconsin. The discussion section briefly relates the model to the differentiation of interests in community growth and change (see Molotch, 1976). It should be stated that the argument developed here is not meant to apply directly to larger centers, where major businesses are less likely to be owned by individuals or families, and where unionization may have an important bearing on incomes. Nor is it the intention of this paper to provide a complete explanation of income distribution at the individual or community level.

METROPOLITAN SPREAD AND RETURNS TO EDUCATION AND EXPERIENCE

Research on income inequality using areal units such as states (Al-Sammarie and Miller, 1967; Aigner and Heins, 1967; Sale, 1974; Chiswick, 1974), counties (Farbman, 1973; Gunther and Ellis, 1977), and cities (Murray, 1969; Frech and Burns, 1971; Betz, 1972) has consistently shown that where incomes are relatively high they are more equally distributed.

In general, it has been impossible to tell whether these results are anything more than a reflection of demographic, educational, and/or occupational variations resulting from a spatial division of labor. However, Chiswick (1974), using census tabulations of income by education for males over 25, derived a measure of returns to education for each state and found that this indicator, which reflects percentage increases in income per year of schooling, was highly associated with state income inequality (r = .77), while the interstate correlation between inequality in schooling and income inequality was relatively low (r = .48). This result was also found when southern states were excluded. Chiswick (1974:69–71) suggests that the greater mobility of people with more education means that they participate in a national labor market, and that their incomes are relatively equal across areas. On the other hand, people with less education, being less mobile geographically (but perhaps more mobile occupationally), are subject to local labor market conditions. Where their incomes are low, average incomes are low and income inequality high.

---

[1] Apart from Mueller (1974) who studied 15 cities, the maximum number of areas or communities used has been 6.

A similar argument may be made with respect to age. Geographic mobility tends to decline as people get older. The social costs of migration increase and, because there are fewer years left in the labor force for older people, larger gains in income are required to make migration economically worthwhile (see Ritchey, 1976). The incomes of older members of the labor force may therefore be more affected by spatial shifts in the economy than the incomes of younger people. In general, incomes increase with age or experience, at least until the age of 40 or 50. However, in poorer areas with declining economies, where there has been little chance of improving one's position over time and where people have been forced to shift occupations, losing expected gains from experience, the effect of age on income may be relatively small.

This suggests a relationship between areal economic conditions and income inequality which is more complex than that envisioned by Chiswick (1974), yet consistent with his results. Because older people tend to have had less schooling, returns to experience and returns to education tend to counterbalance each other in their effects on income inequality—those with less education have the benefit of greater experience, and vice versa. However, in areas of economic decline, greater experience does not compensate for less education and the result is a steeper effect of education on income and a tendency for income inequality to be greater in poorer areas.

Geographers and planners following earlier work by sociologists (e.g., Bogue, 1949) have come to see rural area development to be a function of proximity to growing metropolises. Positive spread effects of centers depend on the vitality and the size of the center and diminish with distance from the center (Berry, 1970; Peet, 1978). Negative or "backwash" effects also occur, involving the flow of capital and younger, better educated workers out of more peripheral areas (Richardson, 1976). Farms on the periphery are more labor intensive and less affluent, as alternative employment opportunities are lacking and capital is less available (Nicholls, 1961). The net effect has been reflected in lower median incomes and lower absolute growth in incomes over time as one moves away from metropolitan centers, up to a distance of 100 miles (Lamb, 1975). Spread effects have increased over the past 25 years as areas on the periphery have become part of the "urban field," specializing in industry, recreation, and other urban-oriented functions, but a large intermetropolitan periphery has remained (Friedmann and Miller, 1965).

This pattern of spread and backwash suggests that the incomes of the young and highly educated should be roughly equal throughout a region, but that older people with low education, caught in declining sectors in peripheral areas and unable to command the wages prevailing in areas of metropolitan spread, should have much lower incomes away from growing centers.

Nonfarm proprietary incomes might be expected to be higher near major cities, but there are factors which equalize these incomes across a region, at least for larger businesses. Thus, while proprietors near a major city are in a richer area, they must also pay higher wages and compete with urban businesses in terms of prices, a factor which results in a low level of retail services relative to population for communities near large cities (Johansen and Fuguitt, 1979). In general, the major effects of metropolitan spread and backwash should be on the incomes of those persons who are older and who have less schooling, tending to make incomes not only lower but also more unequally distributed in areas remote from expanding metropolises.

Commercial Centrality and Proprietary Incomes

Central place theory is concerned with the spatial arrangement of market activities. Places that are commerically more important have functions additional to those found in less central places, and serve fairly well-defined market areas that include these "lower-order" places (Christaller, 1966). While much attention has been devoted to the organization of central places by size, location, and differentiation, (see Berry, 1967; Berry and Pred, 1961), there has been little interest in the patterns of income distribution generated by central places in rural regions.

The thesis put forward here is that greater commerical centrality has relatively little effect on wage and salary incomes but permits larger proprietary incomes, thus tending to make incomes higher and more unequally distributed in commercially more central communities. For the highly educated—because of their participation in regional, state, and even national labor markets—neither community nor area should have a large effect on incomes. For wage earners with less schooling, because of the possibility of commuting, conditions in the labor market area are more important than the commercial importance of their communities. However, proprietary incomes are likely to increase with community commercial centrality for several reasons. First, greater centrality permits larger businesses with economies of scale (Hawley, 1941; Berry and Garrison, 1958) and consequently larger proprietary incomes. Second, commerce is expanding at a faster rate in more central places (Clements, 1978; McGranahan, 1980), contributing to the greater profitability of their businesses. Finally, businesses such as banks, which develop branches, are more likely to have their central offices in places of commercial centrality and their branches in less central places.[2]

This argument does not apply to incomes in health, education, and related government activities, where proprietary incomes are generally not involved. Here, community income effects should be largely compositional, depending on the personnel requirements of hospitals, schools, and government bureaucracies. Although larger units may bring occupational differentiation, communities specializing in social services should have less income inequality, due to the absence of proprietary incomes.

The effects of industry on income distribution would appear to depend on the type of industry. According to the dual economy perspective (see Averitt, 1968; Beck et al., 1978), industry may be divided into a center or core sector—comprised of large, oligopolistic, unionized firms (in which wages are set internally), and a periphery sector—comprised of small, competitive, nonunionized firms (where wages are determined largely by local supply and demand). Thompson (1965), in an extensive discussion of urban income distribution, suggests that, at least where the labor market is tight, high-wage manufacturing not only affects incomes for those employed in these plants but also induces an area wage "roll out," which drives up wages in the rest of the local economy.[3] However, since people with high education are relatively mobile geographically, the area roll out may have less effect on their incomes than on others'. For this reason, and others suggested by Thompson (1965) (such as extensive absentee ownership in high-wage industry), towns and cities dominated by high-wage manufacturing should have higher, more equal income distribution.

This argument is more relevant to urban than rural areas, however. First, the distinction between center and periphery industry has a spatial dimension, with much of the industry in rural regions composed of small, low-wage firms and plants. Second, the wage roll-out effects may depend on a tight labor market, which is generally present only in areas proximate to growing metropolises. And, third, because of intercommunity commuting in rural regions, wage effects, if any, are likely to be diffused throughout an area. Hence, in many rural regions, there may be little effect of industry on wages, either directly or through wage roll outs. However, manufacturing communities may still have lower income inequality than other communities because much of the industry tends to be absentee owned and because of wage uniformity within plants.

---

[2] Thompson (1965) in his discussion of community income distribution also suggests that profits are constrained by market area. He sees size (centrality) as operating on income inequality by affecting the variation in proprietary incomes. Since even in small towns the vast majority of people work for others, the variation between proprietary and wage incomes would seem to be more important.

[3] Some indirect evidence of this is presented in Parcel (1979).

To summarize some of the basic elements of the model: metropolitan spread and backwash have historically resulted in growth near metropolitan centers and decline in peripheral areas. The incomes of those least mobile geographically—the older, less-educated members of the labor force—have been most affected. This has resulted in a tendency for distance from expanding metropolitan centers to be associated with lower incomes for the bottom end of the distribution, making average incomes lower and income distributions more unequal in peripheral places. At the same time, commercial centrality within an area permits higher proprietary incomes while having relatively little effect on wages and salaries. These increases to the top end of the income distribution tend to make incomes higher and more unequal in places of higher centrality.[4]

The following section, an application of the model to northwestern Wisconsin, serves to illustrate the model's relevance for one rural region. The region was not chosen to be representative of all rural regions. In fact, the relevance of the model should vary from region to region, depending on the size and vitality of the proximate metropolises, the natural resources of the region and the location of satellite centers and transportation routes. At the same time, the developmental history of the northwestern Wisconsin region is not unlike others in the Midwest, and there is little reason to expect locational influences on income distribution to be unique to the region.

INCOME DISTRIBUTION IN NORTHWESTERN WISCONSIN

The Region

The study region is a 17-county area comprising the northwest quarter of Wisconsin. It is bounded on the north by Lake Superior, on the west by Minnesota, and on the south by an interstate highway connecting Minneapolis-Saint Paul (lying just off the southwest corner) to Milwaukee and Chicago. The expansion of Minneapolis-Saint Paul (SMSA population, 1970: 1.8 million) has been the dominant force in the region, drawing off business from Superior-Duluth, a small declining metropolis, in the northwest corner of the region, and spreading out along the interstate highway, promoting the growth of the satellite center of Eau Claire-Chippewa Falls (population, 55,000). In accord with the spatial patterns of spread and backwash, three subregions have been delineated: The north, which historically has been an area of heavy outmigration;[5] the east, an intermediate

---

[4] The effects of metropolitan spread and commercial centrality on returns to age, education and proprietorship are not the only factors affecting community income levels and income inequality. Kuznets (1976) shows how demographic composition can have an important bearing on income distribution. One might expect poor areas to have a relatively high proportion of elderly people, which would result in lower incomes and higher inequality. Lincoln and Friedland (1978) propose that intracommunity differentiation both increases with community size and, due to intercommunity specialization, decreases with metropolitan accessibility, and that more differentiated communities should have greater income inequality. (See also Thompson, 1965; Betz, 1972). Thus, the pattern of community income inequality predicted here may result from demographic and occupational composition as well as from the differential effects of location on incomes.

It should also be noted that, although it is assumed here that community income characteristics depend on commercial centrality, metropolitan proximity, and other attributes, these relationships may not be strictly recursive. High incomes, for instance, may induce commercial development but inhibit industrial expansion over time. The major effects, however, would seem to be in the direction specified, across space if not across time.

[5] Superior-Duluth is an exception to the rule that metropolises grow and spread. Due to the decline in

Table 1. Demographic and Economic Indicators for Three Subregions of Northwestern Wisconsin and the Entire State*

	Population 1970 (1940=100)	Median Age 1970	Value Farm Products Per Farm 1974 ($1,000)	Average Weekly Manufacturing Wage 1974	Unemployment Rate 1974
North[a]	79	36.3	12	124	7.3
East	90	39.9	22	143	6.2
South	116	27.2	23	166	4.8
State	141	27.2	25	204	4.6

* These data were gathered at the county level. Because of the influences of the large cities on county statistics, Douglas County (containing Superior) and Eau Claire County have not been included. Sources include United States Census of Population and Agriculture and reports of the Wisconsin Department of Industry, Labor and Human Relations.

[a] North includes Ashland, Bayfield, Burnett, Douglas, Iron, Sawyer and Washburn counties; east, Barron, Clark, Price, Rusk, and Taylor counties; and south, Chippewa, Dunn, Eau Claire, Polk, and St. Croix counties.

area; and the south, which includes the counties lying along the interstate (Table 1). In all three regions, slightly over one-fifth of the workers are employed in manufacturing.

Individual Level Analysis

The first question to be addressed is whether the effects of metropolitan spread and backwash on income have been greater for older people and those with less education than for younger people and those with more education. Using survey data from the region,[6] Table 2 presents the results of regressing the log of personal income on years of schooling, age (in log terms because returns to experience decline with age), dummy variables representing north and east subregions, and interaction terms formed by multiplying education and age by the regional variables.

Note first that, controlling for age and education, there are considerable differences in average incomes among the subregions (Equation 2). The antilog equivalents of the coefficients for north (−.30) and east (−.23) are .74 and .79 and are the estimated ratios of incomes in these subregions to incomes in the south. However, people have not been affected equally. The interaction effects between education and subregion are significant, large, and positive (Equation 3), indicating that the percentage differences in income between those with high and low education are much greater in the north and east than in the south. Age shows the reverse pattern (Equation 4): incomes vary much more by age in the south than elsewhere. The inclusion of the two sets of interaction terms does not improve the prediction, however, since relatively high returns to education and low returns to age are interrelated phenomena (Equation 5).

The importance of these findings can best be seen by comparing the predicted incomes of people very likely to be affected by region—people aged 60 with eight years of education—with the incomes of people likely to be affected only minimally by region—people 30 years of age with sixteen years of education. The predicted incomes using Equation 5:

---

importance of lake transportation and the increase in the importance of Minneapolis-Saint Paul, this SMSA actually lost population from the 1920s until the mid-1970s, and it has generated no apparent spread effects in the northern section of the region.

[6] The data are from 1973 and 1974 surveys on personal well-being in the region, both of which drew samples from all 3 subregions. Together, 13 of the region's 17 counties were covered (2 of the 7 counties in the north and 1 of the 5 in each of the other 2 subregions were omitted). Because part- and full-time employment were not distinguished in the surveys, only employed men between the ages of 21 and 65, living outside of places of 10,000 or over, and with incomes of at least $2,000, are included here. Farmers are excluded because their incomes may be affected by a number of factors other than wage levels (although when they are included the results are strengthened). The (reduced) sample size is 345, of which 63 are self-employed.

Table 2. Personal Income in Northwest Wisconsin by Area, Education, Age and Interactions of Subregion with Education and Age for Men, Ages 21–26, with Nonfarm Employment (N=345)

	Regression Coefficients of Equations Predicting Log of Personal Income*				
	(1)	(2)	(3)	(4)	(5)
Education	.065	.060	.037	.057	.040
Age (Ln)	.226	.263	.276	.426	.396
North Subregion[1]		−.30	−.30	−.30	−.31
East Subregion[1]		−.23	−.20	−.24	−.23
Interaction Terms					
North × Education			.036		.025^{NS}
East × Education			.030^{+}		.036^{NS}
North × Age				−.377	−.305^{NS}
East × Age				−.211^{NS}	−.211^{NS}
R^2	.14	.20	.22	.22	.22
$\bar{R}^2$	.13	.19	.20	.20	.20

[1] Coefficients for subregion represent deviation from south, for people with average age (40) and education (12).

* = All coefficients significant at .05 level unless otherwise marked.

$^{+}$ = P < .10.

	Age: 60 *Education: 8*	Age: 30 *Education 16*
North	$ 6,900	$10,900
East	7,800	11,500
South	11,800	12,300

The subregional differences in estimated incomes for men aged 30 with sixteen years of education are quite small relative to those differences for men aged 60 with eight years of education; this is further reflected in relatively small differences between the age/education groups within the south—especially as compared with the north. Age and education have a correlation of −.33 in this sample. In the south, the effects of these two would appear to balance each other out, but this is far less true in the other two areas. There may be additional factors (such as age and education composition) contributing to greater inequality in the north than in the south, but these interaction effects are clearly important.

The second question to be dealt with at the individual level is the differential effect of commercial centrality on wage and proprietary incomes. Unfortunately, the only measure of centrality in these data is size of place of residence, which is coded as rural open country, village, or city (over 2,500 population). Whether or not a person said he was self-employed is used as the measure of source of income.

From the first equation in Table 3, it is evident that there is little variation in income by community size, at least for this rather crude size breakdown. This result is unexpected, given that larger places are more likely to have schools, hospitals, and larger businesses. While people who are self-employed do not generally have higher incomes (Equation 1), their incomes do appear to be much higher in places with over 2,500 residents, and the inclusion of the interaction terms adds considerably to the variance explained (Equation 2). The incomes of the self-employed are no less affected by area than are the incomes of wage and salary earners (Equation 3), although this may be less true for the self-employed who own large firms and/or who are highly educated.[7]

Community Level Analysis

Community level analysis is used, first, to see if incomes are lower and more unequally distributed in communities located

---

[7] While the interaction effects of subregion with age and education may in part reflect subregional differences in industrial structure, a division of the study sample into core and periphery sector employment (Beck, et al., 1978) showed no evidence of this. In all three subregions, 44% to 45% of the sample works in the core sector. While there is no variation within the region, this percentage in core sector employment is much lower than the 71% found by Beck et al. (1978) for males in their national sample.

Table 3. Personal Income in Northwest Wisconsin by Subregions, Size of Place of Residence, Self- or Wage-Employment, and Interactions of Self-Employment with Size of Place and Area for Men, Ages 21–65, Nonfarm Currently Employed

	Regression Coefficients of Equations Predicting Log of Personal Income ($1,000s)*		
	1	2	3

* Significant at .05 level unless otherwise noted.

in the more peripheral subregions and, second, to explore further the relationships among commercial centrality, size of firm, proprietary incomes, and community income characteristics. For the 92 villages and cities in the region having from 200–7,500 residents in 1970, per capita incomes and Gini indices of inequality have been calculated from income distributions furnished by the Wisconsin Department of Revenue. These are based on 1973 personal taxable incomes, husbands and wives combined, net of business expenses. Because nontaxable transfer payments such as social security are exluded, the proportion of population over 65 is included (but not substantively interpreted) in the analyses reported in this paper.

The log of community commercial employment is used as the measure of commercial centrality. This measure, like employment in industry and social services (health, education, and government), is based on unemployment compensation tax returns filed by employers for the first quarter of 1975 (when public agencies were first required to file). For establishments employing over twenty people, the type of ownership—local or absentee—has been determined.[8] Finally, the ratio of employment to population has been calculated to reflect the extent to which a community is an employment—rather than a residential—center. Analysis of individual data showed that there is considerable commuting in the region, and that the self-employed and highly educated were most likely to live near where they worked. Residential communities, generally the smaller villages, can therefore be expected to have lower (and more equal) incomes than places with high employment-to-population ratios.

The results of regressions of these variables on per capita incomes and income inequality are presented in Table 4.[9] The results show, first, that communities in the northern subregion have the lowest and most unequal incomes and that those in the south have the highest and most equal incomes. (Analysis not shown here indicates, in addition, that the ratio of community to open country incomes follows the same pattern, being higher in the north and east than in the south).

---

[8] Overall, 40% of the employment is commercial, 27% industrial, and 33% social service. Employment in large (over twenty employees) commercial establishments comprises 30% of total commercial employment, of which 26% is in absentee-owned firms. For industry, over 90% of the employment is in large firms, and 62% of this employment is in absentee-owned firms. (Cooperatives have been included as absentee owners because profit income does not remain in the community but, presumably, is returned to farmers living in adjacent rural areas.

[9] Because of problems inherent in the use of ratio variables (Schuessler, 1974; Fuguitt and Lieberson, 1974), these models have been tested in a variety of forms. For instance, the sectoral employment measures were expressed as percentages of total employment in some regressions. Although these and other transformations altered the functional form of the model, the results were essentially the same. The models presented here were chosen because their parameters are easily interpretable and multicollinearity is minimized.

Second, the first pair of equations also shows per capita income and income inequality to be highly related to commercial centrality. However, to the extent that a community specializes in manufacturing or social services, incomes are lower and, in the case of industry, inequality is also lower. Communities that have a relatively high employment-to-population ratio—i.e., that are not "bedroom" communities—have higher and more unequal incomes.

The second pair of equations in Table 4 incorporates effects due to size of firms and absentee ownership. With both the total percentage employed in large (over twenty employees) firms and the percentage employed in large *and* absentee-owned firms in the analysis, the effects of the former are net of the effects of the latter. Thus, the coefficients for the percentage employed in large firms represent, in this context, the effects of having large local firms as opposed to small, primarily local firms. While the concentration of local ownership in large firms has little effect on per capita incomes, it is associated with higher inequality as, according to the rationale, the same proprietary incomes are going to fewer people. Commercial centrality is associated with large commercial firms (r = .67), and this explains part of the relationship between centrality and inequality. The results also indicate that, to the extent that ownership of industry and commerce is absentee, both incomes and inequality are lower because proprietary incomes are going out of the community.[10]

This analysis shows that proprietary incomes are an important component in the distribution of incomes in the region. It gives strong evidence that commercial centrality affects community level and inequality by permitting larger proprietary incomes at the top end of the income distribution. This evidence is reinforced by the absence of similar income effects for industry and social services.

DISCUSSION

This paper has explored the question of how economic opportunities may be structured spatially in rural regions. The model developed here appears to be useful for understanding income distribution in northwestern Wisconsin. The basic theme is that location, in itself, does not have a uniform effect but, rather, influences incomes in distinctly different ways—depending on age, education, and proprietary status. The incomes of the more geographically mobile, young, and highly educated appear to vary little across the region, while the incomes of older people with less schooling vary considerably, according to the pattern of metropolitan spread and backwash. Within subregions, wages and salaries appear to vary little by community, while proprietary incomes increase sharply with commercial centrality. These differences are at least contributing factors in the distribution of income within and among communities. Communities in more peripheral areas have lower per capita incomes and greater income inequality; commercial centrality is associated with higher and more unequally distributed incomes.

The relevance of this model for other regions remains to be tested. As suggested earlier, its relevance should vary, depending on the size and vitality of proximate metropolitan centers and on other regional characteristics. Recent industry and population growth (both nationally and in northwestern Wisconsin) indicates that the era of rural decline may be over. If these trends continue, the effects of metropolitan spread and backwash should

---

inequality are twenty percentage points lower. For these small communities, the current model is clearly more useful.

[10] Following Betz (1972) and Lincoln and Friedland (1978), who suggest that inequality is a reflection of differentiation, a Gibbs-Martin index of differentation $[1 - \Sigma X_i^2/(\Sigma X_i)^2]$ was calculated using eight employment sectors. This measure is related to population and employment, and to income and income inequality, but it adds nothing to the variance explained and, when substituted for the employment measures used here, the R^2 for both income and

eventually become less important.[11] However, other spatial shifts in the economy are occurring and new ones, induced by rising energy costs, for instance, may become pronounced. Again, the income effects should be greater for those least mobile geographically.

The model developed in this paper has implications for the delineation of interests in community growth and change, suggesting that these interests will vary according to education, age, and proprietorship. It is the people with commercial proprietary interests who provide the main force behind communities as "growth machines" (Molotch, 1976), for increased centrality raises their incomes.[12] In contrast, the incomes of people who are young, highly educated, and salaried are little affected by growth in either the community or the subregion. For these people, other concerns such as environmental quality may take precedence. The incomes of wage earners with low education are affected by conditions in the area, but local community centrality is not, in itself, particularly important. Although wage earners and proprietors may generally agree that growth should be promoted, their interests are not necessarily mutual with respect to the kind of growth that occurs. For instance, the development of subregional growth centers may be advantageous to all wage earners in an area, but to only the proprietors in the designated centers.

This paper has been concerned with what may be called the spatial dimension of stratification. While the particular model developed here has been tailored to fit rural regions—and it undoubtedly fits some regions better than others—this study as well as work by Chiswick (1974) and others at the national level suggests that a thorough understanding of the distribution of income in this country will require an understanding of the ways in which opportunities are structured spatially. This, in turn, should lead to a better understanding of community stratification and structure.

[11] Featherman and Hauser (1978) present income attainment equations for the United States, North and South, in 1962 and 1973. In 1962, returns to education for whites were higher in the South than in the North, and the effect of age on income much lower, controlling for a number of other factors. These results are consistent with the model developed here, with the northern section of the country historically an area of spread and the South, an area of economic backwash. However, by 1973, these and other North-South differences had largely disappeared, a change attributed to their now more similar industrial structures. According to the logic of the present paper, the process of economic expansion of the South has been a crucial factor in this change. The South is less the economically peripheral, backwash area that it was, and its expansion (relative to the North) has increased the opportunities for southerners with less education, raising their incomes.

[12] Note that this does not extend to owners of industrial property. To the extent that a firm's wages are determined locally and its sales are independent of local demand, economic growth may, through its impact on local wages, be inimical to industrial interests. Industry and commerce may, therefore, have quite different interests in the community.

COMMENTS

COMPARING STRATIFICATION THEORIES*

(A COMMENT ON ROBINSON AND KELLEY, ASR, FEBRUARY, 1979)

In a recent article Robert Robinson and Jonathan Kelley (1979) attempt to integrate Marx's and Dahrendorf's theories of social stratification with the Blau-Duncan approach, through a quantitative examination of class in the United States and Great Britain. This transfusion of European stratification theory into the dominant SES tradition could be very important, both theoretically and empirically. It is doubly unfortunate, therefore, that Robinson and Kelley's work presents errors of both theory and method which lead them to underestimate the power of the European theories vis-à-vis the Duncan-Blau model, and, hence, understate the utility of the Marxian and Dahrendorfian approaches.

In the following sections we identify errors in three areas of their analysis: specification of the sample; operationalization of the independent variable (class); and operationalization of the major dependent variable (income). Based on a reanalysis of some of the data, we argue that Robinson and Kelley's procedures distort the class models which prevents a useful test of them. Their procedures also generate noncomparable data for the United States and Britain which casts doubt on the validity of their cross-national findings.

1. Sample

To compare three contrasting approaches to stratification in two different countries we need samples that represent the entire spectrum of classes in each society. For the Marxian model, the issue of representativeness is particularly acute because Marx discusses classes in capitalism in the context of polarization between the majority—the proletariat—and a numerically small group of capitalists who are disproportionately represented at the upper tail of the income distribution. Thus Marx's model focuses upon extremes of the income distribution.

Robinson and Kelley select a United States sample, however, which excludes unemployed workers, workers on strike, vacationing and ill workers, and part-time workers. This decision distorts their sample in two ways: First, the unemployed and underemployed occupy a critical position in Marx's analysis of wage-labor; excluding them eliminates an important element in this class model. Second, the exclusion of both part-time and unemployed workers lops the bottom off the income distribution, that is, it eliminates a large proportion of the poor from Robinson and Kelley's sample. Table 1 shows that part-time workers in Robinson and Kelley's survey have a much lower mean family income than full-time workers. This also holds for individual incomes of part-time versus full-time workers.

Adding the unemployed, strikers, etc., to part-time workers increases this divergence in income between those proletarians whom Robinson and Kelley include in their sample and those whom they exclude. In short, Robinson and Kelley propose to test Marx's class theory after first excluding poorer individuals from their sample. Since their major test is to regress income on class, this exclusion of lower-income workers from the sample is quite inappropriate, and biases the test against a Marxian model.

A second issue in sampling concerns the comparability of the United States and British samples. Robinson and Kelley include both full-time and part-time workers in the British sample, while allowing only full-time workers in the United States sample. Not only does this mean that these two samples are not equivalent, it will also, ceteris paribus, lead the Marxian model to perform better on the British data than on the United States data, due to Robinson and Kelley's artifact of attenuating the United States sample. These problems of cross-national noncomparability are compounded by other decisions Robinson and Kelley make, as we show later.

2. Independent Variables

Robinson and Kelley (1979:39) initially define the Marxian class of capitalists as those

Table 1. Groups Included in and Excluded from Robinson and Kelly's United States Sample

Group	N	Mean Family Income	S.D.	T Value	Degrees of Freedom	2-Tail Significance
1976						
A. Full-Time Workers	591	16,076.98	8271.68	5.40	708	<0.001
B. Part-Time Workers	119	11,630.52	7815.52			
A. Full-Time Workers	591	16,076.98	8271.68	7.06	795	<0.001
B. Other Proletarians	206	11,468.44	7472.06			
1974						
A. Full-Time Workers	591	14,703.89	7713.47	4.17	691	<0.001
B. Part-Time Workers	102	11,279.41	7283.36			
A. Full-Time Workers	591	14,703.89	7713.47	5.40	787	<0.001
B. Other Proletarians	198	11,282.82	7721.07			

Note: In each case, group A was included in Robinson and Kelley's sample while group B was excluded. "Other Proletarians" includes workers on strike, or laid off, or looking for a job, part-time workers, ill workers, workers on vacation, and unemployed workers, but does not include students or homemakers or retirees.

Source: National Opinion Research Center, General Social Survey. See NORC (1972).

who own the means of production and who purchase the labor-power of others. They add:

> . . . we will show that capitalists have high incomes *not only* because they own the means of production but also because they exercise authority. The true effects of owning the means of production can only be discerned by controlling (in the usual statistical sense) for authority by making ownership one variable and authority a second variable and using standard multivariate techniques for separating their effects. (Robinson and Kelley, 1979:41)

While theoretically sound, this passage is curious because the NORC data which Robinson and Kelley use for their United States sample contain no questions about ownership of the means of production or about the purchase of others' labor-power. The 1973, 1974, and 1976 NORC surveys contain information only on supervision. Supervision is not synonymous with either ownership of the means of production or employment of others, yet Robinson and Kelley proceed to define Marx's capitalist class in terms of supervision. Having argued for the theoretical separation of authority from ownership, Robinson and Kelley adopt procedures that obfuscate this separation.

In their operationalization of Marx's capitalist class, Robinson and Kelley shift from the notion of ownership of the means of production to control of the means of production. They argue that some managers control the means of production and are therefore capitalists. Robinson and Kelley then generalize that anyone who supervises others and is not him/herself directly responsible to a supervisor is ipso facto a capitalist. This final operationalization is not in any sense equivalent to Marx's concept of the capitalist as owner of the means of production.

For example, if we apply Robinson and Kelley's definition of capitalists (persons who are not themselves directly responsible to a supervisor, but who do supervise others) to equivalent 1977 NORC data, we find that 44% of Robinson and Kelley's "capitalists" are employees, rather than self-employed.

Secondly, Robinson and Kelley's definition of the capitalist class (N = 161) categorizes individuals from an extraordinary assortment of occupations as capitalists. Of Robinson and Kelley's "capitalists" 18.6% are in the census category of professional, technical and kindred workers. These include 7 lawyers, 4 registered nurses, 2 painter/sculptors, and various others. An additional 11.8% of "capitalists" were craftsmen and kindred workers, including 3 carpenters, 2 foremen, 2 automobile mechanics, etc. Eight clerical workers, including 3 secretaries, 2 clerical supervisors, a keypunch operator and others constitute another 5% of the capitalists. Twelve sales workers, including 7 insurance agents or brokers and various salesmen/sales clerks, account for 7.4% of the capitalist class. Service workers including 3

Table 2. Percentage Self-Employed by Class (Full-Time Workers Only)

* As defined by Robinson and Kelley (1979:41, 43).

cooks, 2 janitors, and a nurse's aide, represent 4.4% of the capitalist class, and so on.

In short, over 50% of Robinson and Kelley's "capitalists" worked in census occupations other than management, and (in the 1977 NORC survey) 44% of the "capitalists" were wage-laborers employed by others. This does not prevent Robinson and Kelley, who lack any United States data describing ownership of the means of production (e.g., stock ownership) or data describing employment of others' labor, from declaring that these individuals are capitalists, solely on the basis of their responses regarding direct supervision.[1]

Their operationalization of the petite bourgeoisie is even stranger. Marx used the term petite bourgeoisie to refer to individuals who were self-employed and who lived primarily from their own labor. Typical petit bourgeois occupations are lawyers, doctors, and shopkeepers. Robinson and Kelley (1979:41) operationalize this as persons who are not directly responsible to a supervisor and who do not directly supervise others. Applying Robinson and Kelley's definition of the "petite bourgeoisie" to 1977 NORC data, we find that 61.7% of their petite bourgeoisie are *not* self-employed, despite the fact that self-employment is central to Marx's definition of the petite bourgeoisie. These are the kinds of nonsensical results obtained if Marx's notion of ownership of the means of production is operationalized in terms of one ambiguous survey question concerning direct supervision.

Having constructed their version of Marx's class model, Robinson and Kelley proceed to contrast the class structure of the United States and Britain. They assure their readers that for the British data: "Control over the means of production and authority are operationalized in a manner identical to our classification in the U.S. except that only a dichotomous version of authority is available" (Robinson and Kelley, 1979:51).

Despite this statement, Robinson and Kelley use different operationalizations of Marxian classes for the United States and British data. In the United States data, a capitalist is someone who is not directly responsible to a supervisor but who does supervise other persons. A capitalist from the British survey, however, is someone who is self-employed and employs other persons. These two are not equivalent; as we have seen, there is only a 56% overlap between self-employment and Robinson and Kelley's United States "capitalists." Many managers, foremen, and supervisors in the United States sample are categorized as capitalists, yet persons in these same professions are categorized as *workers* in the British sample unless they were also self-employed and employers of others.

Since the British operationalizations allow for a much closer approximation[2] of Marx's class categories than do the United States operationalizations, it is not surprising that the Marxian class model is empirically stronger for the British data. This cross-national artifact becomes even worse when we consider the major dependent variable, income.

3. The Dependent Variable

A major part of Robinson and Kelley's article is devoted to a comparison of the three stratification theories to account for the observed variance in personal income. We have no objections in principle to this approach, but we differ with Robinson and Kelley's measure of income. Marx argued that proletarians have as their sole source of income the sale of their own labor power; capitalists, however, do not depend solely on their own work because they also appropriate the fruits of others' labor. Robinson and Kelley, though, choose a measure of income for the United States which includes only income from full-time employment. Hence they exclude from their United States analysis the various kinds of non-job-related *capitalist* income—from stocks, bonds, rents, etc. Capitalists and workers are compared solely on their income from full-time jobs. We believe this procedure bears little relation to Marx's theoretical framework, and is bound to weaken the predictive strength of his model.

The extention of this income analysis to the British data is again marred by a lack of comparability. The British survey that Robinson and Kelley used asked for the amount of personal income, with no qualification that such income had to be job-related. One may therefore assume that the various sources of capitalist income were included in addition to salaries and wages.

---

[1] This same survey question distorts Robinson and Kelley's treatment of Dahrendorf. Dahrendorf's concept of an "obey" class makes no distinction between those directly responsible to a supervisor and those only indirectly responsible. Yet for Robinson and Kelley the former become "obey class" members, while the latter are candidates for the "command class." Dahrendorf simply distinguishes between those who wield authority and those who lack it; whether one is directly or indirectly responsible to a supervisor is of no consequence.

[2] Robinson and Kelley do not allow for the existence of capitalists who do not personally employ or supervise workers, but who are capitalists by dint of stock ownership. This important sector of the capitalist class falls through Robinson and Kelley's operationalizations and are lost to their analyses.

Thus at three levels—the sample, the operationalization of class, and the operationalization of income—the United States and British data are quite different. In each case the British operationalizations are theoretically much closer to those required by the Marxian model. Not unexpectedly, then, the Marxian model performs quite well for the British income data, while in its very different United States operationalization it performs less favorably. Robinson and Kelley (1979:51), however, reify this artifact of their data manipulations, and conclude that "Britain is more of a classical capitalist society than the U.S."

In conclusion, while we endorse Robinson and Kelley's appeal for a theoretical and empirical comparison of Marxian, Dahrendorfian, and SES approaches to stratification, we sincerely hope that any such attempt is performed with more theoretical clarity than is demonstrated in Robinson and Kelley's "first step." Given the theoretical and methodological distortions in their analyses, it is doubtful whether their findings should be given any credibility.

SYNTHESIS AND COMPARISON OF STRATIFICATION THEORIES: A REPLY*

In their comment on our article (Robinson and Kelley, 1979) Attewell and Fitzgerald argue that, by defining and operationalizing the Marxian class model as we do, we "underestimate the power of the European theories vis-à-vis the Blau-Duncan model" in the United States data and, thus, bias our comparison with the British data. They do not, however, show that our results are, in fact, distorted. In this reply, we defend our theoretical position and offer a reanalysis which shows that the Marxian model has not been slighted by our definitions. In the course of the discussion, we also reply to their objections to the specification of our sample and our measurement of income.

DEFINITION AND OPERATIONALIZATION OF CONTROL OF THE MEANS OF PRODUCTION

Attewell and Fitzgerald claim that we initially (Robinson and Kelley, 1979:39) defined the Marxian capitalist class as those who both own the means of production and purchase labor power, but later (p. 41) shifted to a definition of the first criterion in terms of "control of the means of production." In fact, from the beginning, our definition is in terms of control. Immediately following our first mention of the Marxian model (p. 39), we state:

> In a modern economy, Marx's criterion of ownership of the means of production may reasonably be expanded to include all forms of control of the means of production, whether they stem from legal ownership or formal control. Thus we include in the capitalist class managing directors who control but do not own the means of production since in practice they have effective control over their firms, can use them to further their own interests, and often own some stock in them. . . .For terminological simplicity we will refer to both owners and managing directors as "controlling the means of production."

Our conceptualization of control encompasses the owner's legal control and the managing director's de facto control. In operationalizing this we employed the following question: "Do you have a supervisor on your job to whom you are directly responsible?" We reasoned that individuals who have no supervisor, or boss, control the means of production, while those who do have a supervisor, or boss, do not. We cautioned (Robinson and Kelley, 1979: fn. 15) that our operationalization was preliminary and that "a small proportion of persons who responded that they have no supervisor may not actually control the means of production but may instead simply be autonomous workers."

Employing this definition and operationalization was preliminary and that "a small proclass as those who control the means of production and exercise authority (that is, have employees or subordinates) and the petite bourgeoisie as those who control the means of production but do not exercise authority

* Regression coefficient is significant at $p < .05$.

(Robinson and Kelley, 1979:41:Table 1). Attewell and Fitzgerald object that both classes include a sizable proportion of persons who are not self-employed—that is, who are not owners of a business. Yet this can hardly be surprising since the concept was intended to encompass those who had de facto control as well as those who owned firms.

One might ask whether we have, in fact, underestimated the importance of Marx's model by including in the capitalist class those who control—but do not own—the means of production. A reanalysis suggests that the answer is no, and that, if anything, our operationalization shows a somewhat greater effect of Marx's model than obtains if ownership is used, instead. The 1977 NORC General Social Survey data (the same data employed by Attewell and Fitzgerald) include a question on self-employment[1] as well as the questions from which our operationalizations of control and authority were derived. These data permit two alternative operationalizations of class in Marx's sense—one based on ownership (operationalized by self-employment as suggested by Attewell and Fitzgerald) and the other on control (as defined in our article). Regressions for U.S. men[2] are shown in Table 1, columns 1 and 2. A comparison of column 1, Table 1, presented here, to Table 3 in our article (Robinson and Kelley, 1979:48), shows that the 1977 data, despite the small number of cases (N = 296 full-time men) compared to our analysis based on the combined NORC 1973, 1974 and 1976 GSS, are generally similar although the effect of education is smaller and that of occupational status is larger. This is apparently due to the greater instability of coefficients in small samples.

Since Attewell and Fitzgerald direct their critique at our comparison of stratification theories, we present standardized coefficients, which show the relative effects of Marx's, Dahrendorf's, and the status models. A comparison of the coefficients in columns 1 and 2 suggests that our operationalization of Marxian class as "control" (.147) has, if anything, a slightly greater impact on men's earnings than does Attewell and Fitzgerald's operationalization as "ownership" (.117). To the extent that Attewell and Fitzgerald's preference for ownership is to be accepted, we have slightly *over*-estimated the importance of Marx's model by our extension.

OCCUPATIONAL COMPOSITION OF THE CAPITALIST AND PETIT BOURGEOIS CLASSES

Attewell and Fitzgerald claim that, because we defined capitalists in terms of control rather than ownership (operationalized as self-employment), our "capitalist class categorizes individuals from an extraordinary assortment of occupations as capitalists." Again, this is not surprising. We (Robinson and Kelley, 1979:42) advanced such a distinction between class and occupation on theoretical grounds:

> Although it is often assumed that occupational standing and class are virtually identical, in fact there is little overlap between them, as both Marx (1893:862–3) and Dahrendorf (1959:138–40) stress. Occupations may be performed in a variety of class contexts. Lawyers, plumbers, or cooks, to name only a few examples, may work on their own account and hire assistants (and so be capitalists in

---

[1] Data on self-employment were unavailable in the 1973, 1974 and 1976 NORC General Social Surveys that we analyzed.

[2] Time and space limitations preclude a reanalysis of women. Our original United States-Britain comparison was made on the basis of samples of men in the two countries.

> the command class), or may work for a large company without any subordinates under them (and so be workers in the obey class), or may work for a large company and have subordinates (and so be workers in the command class), or may work alone on their own account (and so be petit bourgeois and classless).

In Table 2 of our article we (Robinson and Kelley, 1979:46) showed that class and occupation are, in fact, "empirically as well as conceptually distinct." Attewell and Fitzgerald object to our including in the capitalist class such occupations as lawyer, registered nurse, painter, or carpenter. Apparently they have missed our point about occupation and class—that they are virtually unrelated. We also reject Attewell and Fitzgerald's claim that "typical petit bourgeois occupations are lawyers, doctors, and shopkeepers," as another example of their confusion of class and occupation.

It is perhaps necessary to emphasize that the empirical distinctiveness of class and occupation does not arise from our operationalization of control. As Table 2 shows, the distribution of occupations within a capitalist class operationalized as those who are self-employed with employees, as suggested by Attewell and Fitzgerald (see also Wright and Perrone, 1977), includes as wide a range of occupations—for example, lawyer, pharmacist, clergyman, funeral director, sales manager, radio and TV repairman, as obtains when control is used in operationalizing class.[3] Moreover, operationalizing class as ownership, 50% of capitalists fall into occupations other than management, a figure virtually identical to what they find using our measure of control. Furthermore, Wright and Perrone (1977:36) and Kalleberg and Griffin (1980) have also demonstrated the distinctiveness of occupation and ownership (as defined by self-employment) and the first author of this reply has supported this point on data from seven societies (Robinson, 1979:chap. 3).

Underlying Attewell and Fitzgerald's critique is, we believe, a serious misunderstanding of class as Marx conceived it. Their reasoning suggests that they do not view occupations (such as lawyer, plumber, painter, or mechanic), which are not directly engaged in the production of commodities, as belonging to the capitalist class. Yet Marx did not distinguish between productive and nonproductive capitalists or workers in this way:

> The only worker who is productive is one who produces surplus-value for the capitalist, or in other words contributes towards the self-valorization of capital. If we may take an example from outside the sphere of material production, a schoolmaster is a productive worker when, in addition to belabouring the heads of his pupils, he works himself into the ground to enrich the owner of the school. That the latter has laid out his capital in a teaching factory, instead of a sausage factory, makes no difference to the relation. (Marx, 1867, as quoted by Wright, 1976:14)

If individuals produce a service and then sell it at a profit, they are no less capitalists than if they were producers of some material commodity such as automobiles.

Table 2. List of Occupations Comprising the Capitalist Class as Defined by Self-Employment with Employees. Full-Time U. S. Men and Women Only, 1977

Occupation	Percentage of Capitalist Class
Lawyer	2.4%
Dentist	2.4
Pharmacist	4.8
Clergyman	7.1
Funeral director	2.4
Restaurant, cafeteria, and bar manager	2.4
Sales manager and department head, retail trade	2.4
Managers and administrators, not elsewhere classified	42.9
Real estate agent and broker	4.8
Salesman and sales clerks, not elsewhere classified	4.8
Bookkeeper	2.4
Radio and TV repairman	2.4
Painter, construction, and maintenance	2.4
Truck driver	2.4
Freight and material handler	2.4
Farmer (owners and tenants)	7.1
Hairdresser and cosmetologist	4.8
Total	99.5%
Number of cases	(42)

RESTRICTION OF THE SAMPLE

Attewell and Fitzgerald argue that, because we excluded persons who worked part time, or who were on strike, on vacation, ill, or unemployed, we underestimated the effect of the Marxian model since these excluded persons have lower incomes than those we included in the analysis. Although we would have liked to include the unemployed, we had stronger reasons for excluding them. Since our overriding purpose was to synthesize stratification dimensions, a reasonable way of classifying the unemployed had to be found for Dahrendorf's model and for the Blau-Duncan status model. In Dahrendorf's scheme, we thought that such individuals might be included in the classless group since they are not currently part of the industrial authority hierarchy. In the status model, however, Duncan (1961) did not provide an SEI score for unemployed persons, nor did Featherman et al.'s (1975) update which we used in coding occupational status. We rejected the possibility of assigning unemployed persons the status of their usual occupation because it would not reflect their current disadvantaged circumstances. Thus, there was no way of classifying the unemployed in terms of status and, consequently, such individuals had to be excluded. Moreover, while we do not wish to understate the severity of unemployment, the unemployed constitute a relatively small proportion of the total labor force (roughly 6% at the time our data were collected). Thus, we suspect that this omission does not bias the analysis to the extent that Attewell and Fitzgerald claim.

---

[3] Since Attewell and Fitzgerald include both male and female capitalists in their remarks, we have analyzed both of these in Table 2.

Although we were unsuccessful in solving the problem of how to treat the unemployed, Attewell and Fitzgerald provide no solution to this either. They mention no way of handling the unemployed in either the Dahrendorf or status model. Regarding Marx's model, they adopt procedures which muddle an important conceptual distinction in Marx's work. In Attewell and Fitzgerald's Table 1, unemployed persons are grouped with part-time, striking, vacationing, and ill persons and labelled "other proletarians." Yet Marx did not classify the unemployed with part-time workers nor did he classify them with the worker class, as Attewell and Fitzgerald's discussion implies they should have been. Rather, he treated them as a separate class—the *lumpenproletariat,* which he referred to as "refuse of all classes" (Marx 1852:480). An approach which is more consistent with Marx's class analysis would treat the unemployed (but not part-time workers) as a fourth class. Even this solution, however, leaves unsolved the problem of how to treat the unemployed in the Dahrendorf and status models.

Aside from the problems with the unemployed, we agree that, generally, it is best to impose as few restrictions on the sample as possible in conducting an analysis. The selection of a sample must, however, be determined by the purposes of the analysis. Because we (Robinson and Kelley, 1979:fn. 14) wished to compare men and women in the United States data, and because a disproportionate number of women worked only part time, we decided to analyze full-time workers only, though we agree that, generally, part-time and other workers should be included in analyses. In making their arguments, however, Attewell and Fitzgerald overstate the case that the Marxian model would be slighted by our exclusion of these persons. There is just as much reason to believe that members of Dahrendorf's obey class (who exercise no authority) will be underemployed. Consequently, some of the effect of excluding these people should accrue to Dahrendorf's model.

In fact, as a comparison of columns 3 and 4 of Table 1 with columns 1 and 2 shows, adding these excluded persons (but not the unemployed) does not substantially affect the coefficients for the Marxian model (defined as either ownership or control), but it does increase the impact of the Dahrendorf model slightly and decrease the influence of occupational status somewhat. We conclude that the Marxian model is not slighted by our having restricted the sample, and none of our substantive conclusions is altered by this reanalysis.

MEASUREMENT OF INCOME

Attewell and Fitzgerald claim that, by employing a measure of job earnings in the U.S. data, we have biased the results against the Marxian model. They argue that a substantial part of capitalists' income derives from nonjob earnings such as stocks, bonds, rents, etcetera, and that we have underestimated the impact of Marxian class by ignoring such income. We agree that use of such a variable would have been preferable but, unfortunately, it did not exist. Attewell and Fitzgerald fail to mention, however, that in addition to capitalists' income, several sources of workers' income—welfare payments, unemployment compensation, disability payments, and earnings from second jobs—were also excluded. Thus, to a certain extent the excluded sources of income for workers may have counterbalanced those excluded for capitalists.

In fact, this appears to be the case. It is possible to ascertain the extent to which Attewell and Fitzgerald's objection has practical consequences by analyzing the 1977 NORC data. These data include the *personal*-earnings variable, which we employed, as well as a *family*-income variable which asks about income from all sources: "In which of these groups did your total *family* income, from *all* sources, fall last year before taxes, that is?" (italics in original). By analyzing only those men who reported that they were the sole earner in their family, it is possible to employ the family-income variable as a measure of personal income from all sources. This income measure should be slightly inflated because it will include some nonjob income of spouses and children, but this will work in Attewell and

Fitzgerald's favor if their argument is correct. That is, the difference between personal job earnings and personal income from all sources will be even greater because some income from other family members is included. Because of the limited nature of this sample (only about 40% of the men analyzed in columns 3 and 4 of Table 1 fall into this sample) it is inappropriate to compare results from it with those in Table 1. However, by comparing regressions on earnings with those on income *within* this sample, we can ascertain the extent to which the results using income might have differed from those using earnings. Before proceeding to such an analysis, we note that the correlation between job earnings and income (from all sources for men working full or part time, or on strike, on vacation, or ill) is fully .931. Moreover, comparing the mean annual job earnings ($13,891) with the mean annual income from all sources ($14,678) shows that we had excluded only 5.4% of personal income by using a job earnings measure. In Table 3 we present the results of a regression analysis of earnings and income. In the models employing control (columns 1 and 2), though the Marxian model increases slightly and the Dahrendorf model decreases slightly, when income is considered, other variables (education and father's SES) show even larger changes in effect. In the models employing ownership (columns 3 and 4), the Marxian model is more effective on income than on earnings, although the difference in the coefficients for the two models (.039) is far from remarkable—especially in samples of this size (N = 142). Dahrendorf's model decreases slightly (.027), while other variables (education and father's education) experience larger shifts. We conclude that, although there is some truth to the argument that income better captures economic differences between classes, the improvement is far from dramatic and none of our substantive conclusions is altered.

UNITED STATES-BRITAIN COMPARISON

Attewell and Fitzgerald conclude (on the basis of their objections previously discussed) that we have biased the comparison with Britain in such a way that Marxian class appears to have a greater effect in Britain than in the United States. Specifically, they argue that (1) the United States sample did not include part-time persons while the British sample did; (2) the United States class variable was operationalized using an inferior measure of class as control; and (3) the United States income variable excluded nonjob earnings. We will respond to each point in turn.

(1) We included part-time men in the British data because we had no variable which allowed us to exclude them in order to make the British data strictly comparable to the United States data. Since only 9% of United States workers work part time we did not think that this should seriously affect the analysis. As our reanalysis of the United States data has shown (compare columns 3 and 4 of Table 1 with columns 1 and 2), the effect of Marx's model is not increased when part-time men are added. Consequently, the exclusion of part-time men cannot explain the differences we found.

(2) The British data did not allow a perfect replication of our operationalization of control in the United States data and we were forced to operationalize class as ownership in these data. However, as we showed above, ownership is not a superior operationalization of Marxian class; thus, if anything, differences between the countries would have been slightly larger

Table 3. Standardized Regression Coefficients for Models Predicting Personal Job Earnings and Personal Income from All Sources, for U.S. Men Who Are the Sole Earners in Their Family[a]

	Models for Control		Models for Ownership	
Variables	Earnings (1)	Income (2)	Earnings (3)	Income (4)
Marx: Control (cols. 1 and 2) or Ownership (cols. 3 and 4)	.138*	.153*	.115	.154*
Dahrendorf: Authority	.199*	.178*	.223*	.196*
Father's education	.084	.054	.080	.048
Father's occupational status	.039	.034	.023	.015
Education	.072	.146*	.091	.171*
Occupational status	.193*	.197*	.173*	.173*
Percentage of variance explained R^2	20.6%	23.6%	20.3%	23.8%
Number of cases	142	142	142	142

[a] Includes full-time and part-time persons; and persons on strike, on vacation, and temporarily ill.

* Regression coefficient is significant at $p < .05$.

had we used ownership in the United States data.

(3) It is true that the United States earnings measure did not capture income from nonjob sources. In the United States data, however, we have shown that there is little real difference between the results on earnings and those on income. Differences between the United States and Britain (of the magnitude we found) would not disappear when income is used instead of earnings.

To conclude this point, our finding (Robinson and Kelley, 1979:51) that Britain was a more classical capitalist society rested on the fact that "control of the means of production is more important than authority in Britain," meaning that the classical Marxian model in terms of relations of production is more important than Dahrendorf's more recent model in terms of authority. The standardized coefficients reported in Table 3 of our article (p. 48) show that Marx's model (.225) was relatively more important than Dahrendorf's (.133) in Britain, but that Dahrendorf's model (.218) was relatively more important than Marx's (.150) in the United States. In none of the reanalyses of United States data in Tables 1 and 3 does the dominance of Dahrendorf's model over Marx's disappear. Since the British results are unchallenged by Attewell and Fitzgerald, we see no reason to abandon our original conclusion that Marxian class is relatively more important in Britain than in the United States.

CONCLUSION

Attewell and Fitzgerald have raised some interesting conceptual issues which have enabled us to offer further support for our conclusions and for the synthesis of stratification dimensions which we proposed. Reanalyses—using an alternative operationalization of the Marxian model, different samples, and a different economic measure—resulted in only minor discrepancies from our reported results and altered none of our conclusions. On some points, however—particularly the inclusion of part-time workers and the use of income from all sources—we agree with our critics and urge that future research take these considerations into account.

In closing, we would emphasize that, as we clearly stated throughout the article, we were attempting a *merger* of the class and status traditions. To a considerable degree, Attewell and Fitzgerald have misinterpreted us as having been more concerned with a *comparison* of these. Our primary intention was not so much to claim to establish the superiority of one of these theories over the others as it was to show that much is to be gained by integrating all three. From this point of view it is noticeable that Attewell and Fitzgerald fail to discuss the implications of their objections in practice for the Blau-Duncan status model and refer to the Dahrendorf model only in a footnote.[4] Instead, they continually object that the Marxian model in particular has been slighted. We have shown that their objections on this point are not as substantial as they imagine. We believe that more might have been gained by solving the unresolved questions that arise from attempts at synthesis such as our article provides.

[4] It is revealing that in their one reference to Dahrendorf's model they are confused with regard to the question we employed in operationalizing this. They remark that:

> This same survey question distorts Robinson and Kelley's treatment of Dahrendorf. Dahrendorf's concept of an obey class makes no distinction between those directly responsible to a supervisor and those only indirectly responsible. Yet for Robinson and Kelley the former become "obey class" members while the latter are candidates for the "command class."

In fact, we distinguished between the command and obey classes not on the basis of responsibility to a supervisor but on the basis of an entirely different question:

"In your job, do you supervise anyone who is directly responsible to you?" (pp. 44, 46:Table 2).

This confusion on their part may be the basis of their objection that "having argued for the theoretical separation of authority from ownership, Robinson and Kelley adopt procedures which obfuscate this separation."

EMPIRICAL VERIFICATION AND BLACK'S *THE BEHAVIOR OF LAW*[*]

(COMMENT ON GOTTFREDSON AND HINDELANG, ASR, FEBRUARY, 1979)

Donald Black's (1976) *The Behavior of Law* was a major contribution to sociology because of the integrative way it brought together propositions about stratification, morphology, culture, organization, and social control to explain variations across time and space in the quantity of law. At last the sociology of law had a genuine theory which could be a focus for formerly directionless empirical work. The strength of *The Behavior of Law* lay in the fact that because it was in explicit propositional form, it was eminently testable.

Sadly, however, in his recent contribution to *ASR*, Black (1979), out of his own mouth, compromised the value of his theory. Incidentally, in his effort to defend *The Behavior of Law* against a nonsupportive empirical test by Gottfredson and Hindelang (1979a), Black has also neutralized the considerable worth of some of his earlier work (Black, 1970; 1971). This comment is, inter alia, a plea for sociologists to continue to see value in Black's work by ignoring his comment in *ASR*.

Gottfredson and Hindelang (1979a) have used victim survey data to test whether, in accord with Black's theory, the wealthy, the employed, the married, are more likely to report to the police events regarded as crimes than are various other groups. The test seemed reasonable as Black states clearly that "a complaint to a legal official, for example, is more law than no complaint" (Black, 1976:3). However, in his *ASR* comment, Black rejects Gottfredson and Hindelang's use of victim survey data because such surveys require subjects to report only incidents they consider to be "crimes." Hence, the data show only whether people called the police when they considered an incident a crime, not whether some incidents were more or less likely to be interpreted as crimes in the first place. While victim survey data certainly ignore the crucial first-stage labelling process, either the second-stage decision to call the police, given the labelling of the event as a crime, must be relevant to the theory or the theory must become less general than we thought it to be. Gottfredson and Hindelang were able to show that Black did intend the theory to have this level of generality; that he did intend the theory to make predictions about the quantity of law conditional upon the incident having reached some prior stage of processing; and that he did intend victim survey data to be relevant to testing the theory (since Black himself cites such data in support of it).

Black's reversal to the position that his theory cannot explain increments in the quantity of law from one stage of criminal processing to another both limits its generality and renders it untestable in any practical sense. Black (1979) suggests that a relevant test will gather "data based on direct and unobtrusive observation" to ascertain whether any particular type of incident will be more often dealt with legally by one group than another. Black does not address himself to the problem of which types of incidents will be selected for "direct and unobtrusive observation," and how such selection might fundamentally affect conclusions drawn.

In practical terms, we can never get into the offices, the bedrooms, and the boardrooms in order to observe an unbiased sample of the quantity of law arising from "the universe of incidents people experience in their everyday lives" (Black, 1979:20). Through his *ASR* comment Black has transformed what was a testable general theory about increments in the quantity of law into an untestable collection of ideas.

Gottfredson and Hindelang's examination of reporting of crimes to the police uncovered little support for Black's theory as originally stated. What they did find was that the "seriousness" of the offense, as measured by the Sellin-Wolfgang (1964) index was strongly predictive of the quantity of law. Black (1979) correctly retorted that perceived seriousness is a matter of value, not fact; a response to crime, not a characteristic of it. Gottfredson and Hindelang have therefore simply explained one response to crime with another. Black makes much of this. He likens it to explaining the response to an idea with its "truth." Black seems to be suggesting that there is something inherently unsound about this. If one were to say that Donald Black never wrote a book called *The Behavior of Law*, sociologists would reject this assertion because it is not true. In this case, explaining the rejection of the idea with its lack of truth would not only be sound, but it would also be the best explanation possible. The problem with Gottfredson and Hindelang's explanation is not that it is unsound, but that it is banal.

---

It is hardly telling for Gottfredson and Hindelang to denigrate the predictive power of Black's theory by suggesting that the gravity of the infraction against legal norms is a better predictor than Black's stratification, morphology, culture, organization, and social control. Imagine a critique of a theory about what training method is best for weightlifters which points out that how heavy the weights are is a better predictor than are training methods used.

Black's more general point is that Gottfredson and Hindelang's preoccupation with seriousness is evidence that the sociology of law has yet to escape the common sense of the people it studies. This point is well taken. However, the blanket rejection by Black of the use of the seriousness concept, to the point of repudiating his own studies on the severity of sentencing controlling for seriousness (Black, 1970; 1971), goes too far. In the weightlifting analogy above, while it is banal to use weight as an *explanation*, it would be negligent not to use weight as a *control*. Similarly, a study of sentencing which fails to control for the perceived seriousness of the offense is methodologically unsound since the purpose of such work is to determine whether incidents which are perceived as equally serious when decontextualized are dealt with as incidents of unequal seriousness when placed in certain social contexts.

Black persuasively hammers home the seriousness question because it is the weakest part of Gottfredson and Hindelang's (1979a) analysis. However, Gottfredson and Hindelang (1979b:4) correctly point out that even if seriousness variations were deemed irrelevant to Black's propositions, then the validity of the propositions should be assessed by collapsing across the rows (representing different seriousness levels) in their tables. When this is done, the fact remains that the data provide little support for the propositions.

Taking Black's theory in its "proximally conditional" form, data from the Australian crime victims survey will now be used to confront the same propositions selected by Gottfredson and Hindelang for test on American data. The importance of testing the theory of law in a variety of cultures hardly needs to be argued. The methodology of the survey has been described in detail elsewhere (Australian Bureau of Statistics, 1979; Braithwaite and Biles, in press), and is not substantially different from that of the American surveys.

The data have not been disaggregated by seriousness, but have been disaggregated by offense in tables which are not presented in the text. In an attempt to strengthen the generalizability of Gottfredson and Hindelang's empirical test, this replication is on a wider selection of offense types—motor vehicle theft, robbery with violence, theft, break and enter, rape and attempted rape, assault, and nuisance telephone calls, as well as fraud, forgery, and false pretenses.

The first proposition tested by Gottfredson and Hindelang was that the quantity of law varies directly with social rank. Their data, contrary to the theory, show no relationship between family income and reporting to the police. Table 1, part A, shows that in the Australian data there is also no association between household income and reporting to the police. This remains true for seven of the eight offense types when totals are disaggregated by offense. The notable exception is the category of fraud, forgery, and false pretenses which shows a markedly higher rate of reporting to the police among high-income victims.

The second key proposition addressed by Gottfredson and Hindelang is that law is inactive among intimates and is used increasingly as relational distance increases. Black has predicted that since, up to a point, relational distance will increase with city size, the quantity of law will be positively associated with city size. Gottfredson and Hindelang found that, if anything, the reverse was slightly the case. From Table 1, part B, it can be seen that, in Australia also, the data do not support the prediction that reporting to the police will be greater in larger cities. Assault was the only individual offense type which showed a trend in support of the prediction. Assault was twice as likely to be reported to the police in cities over a million than in cities and towns under 50,000.

A more direct way of tapping the relational distance aspect of morphology than that tested

Table 1. Percentage of Victimizations Reported to the Police, by Selected Predictors

A. Weekly Household Income

<$80	$80–139	$140–199	$200–259	$260–339	>$340
34%	31%	43%	38%	34%	41%

B. City Size

500–50,000	50,000–100,000	100,000–500,000	500,000–1,000,000	>1,000,000
33%	43%	41%	38%	37%

C. Residential Mobility

Low	Medium	High
37%	36%	39%

D. Victim's Knowledge of Offenders

Knew at least one offender	All strangers

by Gottfredson and Hindelang is through the residential mobility of the respondent in the years preceding the interview. Respondents who have been geographically mobile should be at a greater relational distance from those around them than people who have lived in the same spot all of their lives. Table 1, part C, shows no relationship between an Australian Bureau of Statistics' residential mobility index and reporting to the police. Nor was there a tendency for high residential mobility to be associated with high reporting to the police on any of the eight individual offenses.

Relational distance is clearly greater in the situation in which offender and victim are strangers than in one in which they are acquainted. While Gottfredson and Hindelang showed only a moderate tendency for offenses to be more likely to be reported when the offender was a stranger, this tendency was quite strong in the Australian data (Table 1, part D). Moreover, the Australian data clearly suggest (Table 1, part E) that where the offender is more intimately known to the victim (family member, close friend) the offense is less likely to be reported than where the offender is less intimately known (speaking acquaintance, knew only by sight).

The next proposition tested is that law varies directly with integration into the center of social life. Black specifically proposes that married and employed people are more integrated than unmarried and unemployed people. Gottfredson and Hindelang found support for the prediction that married people would be more likely to report offenses, but they found no support for higher reporting by those employed compared with those unemployed. The support for Black's theory on the marital status question was not replicated on the Australian data. Apart from a tendency for separated or divorced respondents to report more victimizations to the police, there was little variation according to marital status (Table 1, part F). The one exception by offense was with assault. Respondents who had never been married reported assault victimizations to the police at only half the rate of both those who were married and those who were separated or divorced.

On the employment variable, the Black prediction is supported by the Australian data. People working part time were more likely to report offenses than the unemployed, and people working full time more likely to do so than both people in part-time employment and the unemployed (Table 1, part G). In the present study, persons keeping house were classified as "not in the work force," for the purposes of testing Black's prediction about morphology, whereas Gottfredson and Hindelang classified these people as "employed." Clearly, if persons keeping house had been classified as employed in the present study, the trend supportive of Black would have been greatly diminished.

Black's proposition that law varies directly with culture was operationalized through the indicator of culture suggested by Black: level of education. Gottfredson and Hindelang found a weak positive association between education and reporting to the police. This trend receives strong confirmation in the Australian data (Table 1, part H), and there were no individual offense types which provided significant exceptions to the aggregate trend.

Black hypothesized that "law is greater in a direction toward less organization." In operational terms, Black suggested that more organized offenders (a group of offenders) are more likely to have the law used against them than less organized offenders (a lone offender). Moreover, more organized victims are more likely to use the law than less organized victims. Data are not available from the Australian victims survey on number of victims. However, data are available on the number of offenders. Contrary to Black's prediction, the Australian data show a strong tendency (consistent across offense types) for recourse to the criminal justice system to increase as the number of offenders increases (Table 1, part I). This contrasts with only a very slight tendency in the same direction in Gottfredson and Hindelang's data.

The theory of law asserts that, in settings which permit people to continuously observe and react to each other's conduct, law is less important as a mechanism of social control. "When people go to sleep, for instance, most social control relaxes as well and law increases" (Black, 1976:110). Consistent with this prediction, for both the American and Australian data there were clear tendencies for reporting to the police to be greater for offenses occurring between midnight and 6 A.M. (Table 1, part J).

More crucially, Black maintains that in private settings more nonlegal social control exists, so less law is required than in public settings. Gottfredson and Hindelang produced the surprising finding that their most public setting ("on the street") evidenced a lower rate of reporting to the police than their most private setting ("own home"). Table 1, part K, shows that in the Australian survey the expected finding—that "inside home" and "near home" had lower reporting rates than "outside public areas"—applied. However, "at work"—a more private setting than "outside public areas"—showed the highest reporting rate of all settings.

In summary, the data from the Australian national crime victims survey are almost as discouraging as data from the United States survey in the way in which they refute most of the predictions which have been derived from Black's *The Behavior of Law*. These tests—even though they are on more massive data sets than would be available for any alternative type of verification—are only very partial tests of a theory meant to apply to many other domains. The theory is relevant to the social construction of the event as a crime which occurs prior to a decision about reporting to the police, to a number of stages of processing through the criminal justice system which are subsequent to reporting to the police, and to an infinitely wider range of justiciable types of conduct than the eight which are the subject of this paper and the four which are the subject of Gottfredson and Hindelang's paper. It is a pity that Black has so counterproductively erected the barricades at the first discovery of disconfirmatory data. It may be that his theory can accommodate them.

TRITE BUT TRUE*

(RESPONSE TO BRAITHWAITE AND BILES)

Braithwaite and Biles support our critique of Black's (1979) response to our test (Gottfredson and Hindelang, 1979a) of his theory found in *The Behavior of Law* (1976). They find value in, and essentially replicate, our empirical work.[1] They also see the difficulty in reconciling Black's original presentation of his theory with his subsequent defense of it, and they agree with our argument that to accept Black's "explication" is to accept the conclusion that his theory is not falsifiable.[2] For all these reasons we quite naturally agree with the bulk of Braithwaite and Biles's comment on our paper.

With respect to our use of the concept, "seriousness," however, Braithwaite and Biles restate the position adopted by Black in his comment on our paper. This position, central to the labelling approach to law, is that legal reactions can be explained without reference to individual conduct. Black (1976; 1979) adopts this labelling premise, and when we invoke a measure of conduct and its consequences (the Sellin-Wolfgang [1964] seriousness scale) as a rival hypothesis he counters with the argument that we have explained one response to crime with another (Black, 1979:25). Braithwaite and Biles repeat this assertion, telling us that the seriousness measure we used is "a response to crime, not a characteristic of it" (1980:335).

This interpretation of our use of seriousness has little connection with what we did. However, a theory that denies the relevance of conduct, but which is confronted with evidence of its superior predictive power relative to propositions derived from the theory, is left with few alternative strategies other than to define the rival hypothesis as synonymous with the criterion.[3] Thus, Black (1979) and now Braithwaite and Biles (1980:335) argue that seriousness cannot be used to explain calls to the police because, in effect, seriousness is the same thing as calls to the police (and therefore is a "banal" explanation).[4]

[1] We are, however, prohibited from appreciating the full significance of their data for Black's theory because they are not fully displayed. It is usually standard practice to indicate the numbers of cases upon which percentages are based when offering data as a test of ideas. In the absence of these numbers, and in the absence of a measure of association, we are not able to judge the relevance of some of the tables they present to the theory. (The total sample may be sufficiently large for some of the tables presented, but we are, quite frankly, unsure about those which rely on small parts of their data—e.g., Table 1, part "E".)

[2] Braithwaite and Biles (1980) suggest that Black's (1976) theory, when viewed in its "proximally conditional" form (Gottfredson and Hindelang, 1979b), is of research interest and therefore sociologists should ignore Black's (1979) discussion of his theory in relation to our work. Although we agree with their premise, it is difficult to abide by their conclusion. After all, the theorist must be the ultimate arbiter of "what the theory means" in such jurisdictional disputes. Thus, we are forced to conclude that the inconsistencies (apparent to us and to Braithwaite and Biles) between Black's presentation and defense of his theory are resolved by Black's (1979) response. If his response is accepted, then, for the reasons stated in Gottfredson and Hindelang (1979b), Black's collection of ideas is not falsifiable; in any event, it can hardly be ignored, as Braithwaite and Biles suggest (1980:334).

[3] A priori, it would have seemed that this strategy would be more persuasive when the theory being tested also is predictive of the criterion. In such cases the field must choose between empirically established, but theoretically incompatible, predictors. But apparently this strategy is also useful in cases—such as this—in which one of the competitors has virtually no demonstrated explanatory power with respect to the criterion (i.e., Black's [1976] theory, in relation to calling the police).

The labelling perspective has other strategies that are useful for coping with the problem that conduct is a major correlate of legal reaction. Some of these strategies—such as invoking the claim that even a trivial amount of explained variance is of theoretical interest—have been discussed in the literature (e.g., Tittle, 1975).

[4] Braithwaite and Biles confuse us with their attempt to mediate the dispute between ourselves and

But, as we pointed out when Black (1979) attempted this definitional substitution, we did not use seriousness in the way suggested. The measure we used, the Sellin-Wolfgang scale, was not based on judgments of the respondents in our surveys about the victimization they experienced. If the survey victims had evaluated the seriousness of their own victimizations, there would be *some* truth to the statement (Black, 1979; Braithwaite and Biles, 1980:335) that we "explained one response to crime (the victim's decision to call the police) with another (the *victim's* seriousness estimate). But we did not use a measure like that. The one we used has two components.

The first component relates to the objective characteristics of the crime: how much injury was inflicted, how much financial loss was involved, whether a weapon was used, etc. This component distinguishes incidents that differ with respect to conduct. As we have shown elsewhere (Hindelang and Gottfredson, 1976), by themselves these differences predict calls to the police. That is, even divorced from their association with value judgments, these differences—such as whether or not a gun was present, whether or not injury occurred, or whether or not there was a loss of property in the victimization—are associated with reports to the police. Black (1979), and now Braithwaite and Biles (1980), refer to these differences in conduct as "a matter of value, not fact." In our view, whatever label one chooses to pin on these objective differences in criminal events, the empirical finding that conduct differences predict calls to the police poses a fundamental challenge to all theories (*The Behavior of Law* included) that claim such differences are irrelevant to understanding legal reactions. *That* is why they are important empirical findings, albeit "obvious" ones.

Furthermore, the argument that these offender conduct differences are synonymous with legal reactions (e.g., calling the police, arrest and sentencing) cannot be consistent logically with the theoretical position that they are also uncorrelated with legal reactions. For example, Black's (1976:31) theoretical contention that his principles "... apply whatever the actual behavior of the lower ranks . . . since their conduct is more likely to be defined as illegal no matter what they do," is logically incompatible with his argument that offender conduct differences are just another way of conceiving of the criterion. In the former case we expect no correlation between legal reaction and conduct, in the latter a substantial correlation.

The second component of the Sellin-Wolfgang scale, the scale we used to measure seriousness, is a series of weights applied to these conduct differences. The origin of these weights, and the general intergroup consistency with respect to rank ordering that has been found, are well known (see Gottfredson and Hindelang, 1979a for citations).

Once it is admitted that conduct is a competitor to theories of legal reaction, the question arises as to how it is to be measured and tested against the criterion. As we pointed out (1979b) there are far too many combinations of conduct differences in the data we used, to control them all simultaneously. The weights provided in the Sellin-Wolfgang scores provided a solution to this problem. They permit the scaling of some of these differences along a single dimension—consensually defined seriousness. Thus, from an empirical point of view, these scale values organize the data. From a theoretical point of view, we argued that the gravity of the infraction against legal norms should condition the victim's belief that the conduct warranted the invocation of state social control systems.[5]

The findings that seriousness predicts calls to the police and other legal reactions are central data for the sociology of law. They are also

---

Black, when they state that, whereas seriousness should not be used as an explanatory variable, it should be used as a control variable—otherwise the study will be "methodologically unsound." Why a variable that is not explanatory—in some sense—should be controlled in these types of studies is quite unclear to us. (The answer, it seems, is that when a variable is obvious—i.e., "what everyone knows"—sophisticated sociological *theory* should ignore it, but *researchers* testing these theories better not.) It is also a mystery to us why Braithwaite and Biles would argue that seriousness should be controlled in studies of legal reaction when they themselves define it earlier as a "response to crime, not a characteristic of it." If "seriousness" and "legal reaction" are in some sense synonymous, as Braithwaite and Biles appear to argue, then their suggestion that it would be "negligent" not to control for seriousness is a suggestion that in tabular analyses we restrict the range on our criterion variable.

[5] Contrary to Black (1979:4)—and now Braithwaite and Biles (1980:335)—we define, measure, and use the concept "seriousness" apart from the dependent variable. *They* are thus in the position of arguing that since seriousness is the same thing as the criterion it must be perfectly related to it. We see it as an explanatory concept, but not as a sufficient cause, and thus can tolerate the lack of perfect association. In fact, our data indicate there is much left to be explained after seriousness is taken into account, a finding that constitutes a major challenge for the sociology of law.

"obvious," "banal," and "commonsensical." Denying the relevance of the obvious may be fashionable among some sociologists, but it is not necessarily the best way to construct useful theory. Denying the relevance of conduct to the explanation of legal reactions has led to the construction of a body of theories that do not work very well to predict the phenomena of interest. It is our guess that such poor prediction will continue to be the case in this field, so long as some sociologists choose to claim that behavioral differences cannot be measured and that "what everybody knows" necessarily lacks the profundity to rise to the level of science.

IS THE STATUS STRUCTURE IN THE UNITED STATES REALLY MORE FLUID FOR WOMEN THAN FOR MEN?*

(COMMENT ON GLENN, ROSS, AND TULLY, ASR, OCTOBER, 1974)

Three mid-1970s articles in the *American Sociological Review* reported research in which men's intergenerational mobility was measured in the usual way (by comparing the occupational prestige of fathers and sons) and married women's mobility was measured by comparing the occupational prestige of their fathers and husbands (Tyree and Treas, 1974; Glenn et al., 1974; Chase, 1975). All three studies found greater mobility among the women than among the men. Stated differently, status of origin correlated more highly with status of destination among the men (Glenn et al., 1974: Table 3)[1]—an indication of greater intergenerational transmission of status among the men, at least along the dimensions of status taken into account by the studies.

A statement (written by the first author—who is also the first author of this comment) in the conclusions section of the Glenn et al. (1974) article asserts that, if there are not substantial errors in the data reported in the article, "the status structure in the United States is substantially more fluid than the male data alone would indicate. . . ." This conclusion has been widely quoted and paraphrased in textbooks and other publications. However, the data reported by Glenn et al. (1974) (and in the other publications cited above) do not adequately support that conclusion. As Glenn et al. (1974) point out earlier in their article, women may experience intergenerational mobility in two important ways: through marriage, and through their own achievements (or lack of such).[2] The latter kind of mobility is in no way measured by the three studies. Furthermore, mobility studies which use only the occupational prestige of the family head as the indicator of the status of the family of orientation and the family of procreation fail to deal with several important dimensions of status, the most important of which are perhaps the economic dimensions. Therefore, the conclusion quoted here, for which Glenn is responsible, is premature. The status structure may well be

The data reported in this paper are from the 1973 through 1977 General Social Surveys conducted by the National Opinion Research Center with grants from the National Science Foundation. The authors are solely responsible for the tabulations, analyses, and interpretations presented here.

[1] Of course, the correlation of origins with destinations is not in all cases an accurate indicator of the relative amounts of mobility experienced by two compared populations, but it is accurate if the origins and destinations distributions are the same for the two populations and is fairly accurate if the distributions are similar.

[2] Of course, men may also experience mobility through both of these means, but marriage has traditionally been a less important means of mobility for men than for women.

Table 1. Median Family Income, by Sex and Level of Origin, Married White Persons Ages 25–54, Combined Data from United States National Surveys, 1973–1977

Level of Origin (Father's Occupational Prestige)*	Median Family Income

less fluid for women than for men when mobility through personal achievement and mobility through marriage are both taken into account for both sexes and when dimensions of status not accurately measured by the occupational prestige of the male family head are considered.

In this comment, we report evidence which very strongly suggests, although it does not absolutely prove, that among whites in the United States, there has been greater intergenerational transmission of economic status among women than among men. The evidence is less than absolutely conclusive, because intergenerational economic mobility cannot be directly measured by use of the kind of retrospective survey data which has been used for occupational mobility studies.[3] It is unlikely that many adults are able to report even roughly accurate information on the income and other dimensions of the economic status of their families of orientation when they were children and adolescents. Even if they could do so, income data for different years are incomparable, and thus it would be very difficult to do a meaningful income mobility study with an age heterogeneous sample.

However, it is possible to make a reasonable inference about the rank order of men and women in amount of intergenerational economic mobility without measuring the mobility for either sex. This is possible because the males and females in each birth cohort whose fathers had the same occupations, or had the same level of occupational prestige, must have had, as aggregates, families of orientation which had very nearly the same distributions on economic status. Therefore, if the patterns of intergenerational economic mobility of males and females have been the same, or nearly so, males and females in the same birth cohorts whose fathers had about the same occupational prestige should have, as adults, about the same distributions on economic status. Furthermore, the correlation of father's occupational prestige with measures of current family economic status should be about the same for both sexes, and the regression of the latter variable on the former should not vary by sex.

We have investigated the relationship between father's occupational prestige, as indicated by the Hodge-Rossi-Siegel Occupational Prestige Scores (Siegel, 1971), and reported family income by use of data from the 1973 though 1977 General Social Surveys conducted by the National Opinion Research Center (Davis, 1978).[4] In Tables 1 and 2, here, we report aspects of the relationship, by sex, for married whites ages 25–54.[5] The data are restricted to married persons, since "family income" has a different meaning for married and unmarried persons, being the same as personal income for most unmarried persons. However, since one might suspect that differential selection of males and females into (and retention in) marriage might produce differences in the male and female data, we have conducted supplementary tabulations and analyses including persons of all marital statuses.[6] The resulting

---

[3] Very few studies of intergenerational economic mobility have been attempted. (For the results of one attempt, see Huber and Form, 1973:Appendix 2).

[4] The cumulative GSS file provides data gathered by the 1972 and 1978 surveys, which we did not use because the 1972 income data are coded differently and because we had reservations about pooling income data gathered over a period of six years.

[5] We excluded nonwhites as there are reasons to suspect that sex differences in patterns of intergenerational mobility may differ between blacks and whites and as an insufficient number of black respondents precluded a separate study of blacks.

[6] It is important that the distributions of father's occupational prestige were very similar for the males and females. For instance, among married persons, the means were 39.7 and 39.6 for males and females, respectively, and the standard deviations were 12.2 and 12.6. The distributions of family income were also very similar (see the further discussion in this text).

data are not reported in tabular form but are summarized briefly below.

FINDINGS

The data in Table 1 show a male/female difference in the family incomes of white persons whose fathers had similar occupational prestige. Among persons whose fathers had low occupational prestige, the women had the lower median family incomes; among persons whose fathers had high occupational prestige, the women had the higher median family incomes. In other words, it appears that females who had origins both high and low in the economic hierarchy were more likely to remain near their level of origin than were the males of the same origins. High-status families, as a whole, were apparently better able to confer high economic standing on their daughters than on their sons, and low-status families apparently tended to confer a greater economic handicap on their daughters than on their sons.

From the data in Table 1 alone, one cannot be confident that the observed male/female differences did not result from sampling variability. However, the correlation and regression data in Table 2, to which we apply significance tests, corroborate the differences shown in Table 1. The data from each General Social Survey conducted from 1973 to 1977 show a stronger relationship for women than for men and, thus, indicate greater intergenerational transmission of status for the women. The data from the combined 1973–1977 file show the regression of family income on father's occupational prestige to be more than twice as great for females as for males and show the percentage of variance explained to be almost five times as great for females (6.1) as for males (1.3).

By making use of the fact that the direction of the differences is the same in the data from each of the five independently drawn samples, we were able to compute a joint two-tailed probability (significance level) for the male/female differences in the correlation and regression coefficients.[7] The probabilities, reported in the notes to Table 2, are both lower than .0002. Therefore, one can be highly confident that the relationship was stronger for women than for men in the population.

The analyses conducted with respondents of all marital statuses yielded results very similar to those shown in Tables 1 and 2 and, thus, it does not seem likely that sex differences in the mobility-proneness of persons selected into marriage account for the observed male/female differences. For instance, in the data for persons of all marital statuses, the difference in median family income of persons from the lowest and the highest levels of origin is $9,138 for females but only $3,339 for males. The correlation of father's occupational prestige with reported family income in the data from the combined 1973–1977 file is .092 for males and .205 for females, and the corresponding regression coefficients are 58.07 and 130.85.

---

[7] The joint probability is computed by multiplying across the one-tailed probabilities obtained for the separate surveys and doubling the product to obtain the two-tailed significance level. To illustrate, the probability that two independently drawn samples would both show differences in the same direction significant at the .05 level or lower (one-tailed), if there were no difference in the population, is $.05^2 \times 2 = .005$. By the same logic, the probability that five independently drawn samples would all show like-signed differences significant at the .05 level is $.05^5 \times 2 = .0000006$.

We multiplied all standard errors by 1.3 as an adjustment for the cluster design of the samples (see Kish, 1965).

Another possible problem grows out of the fact that family income is normally higher for middle-aged persons than for young adults and, thus, for our purposes is not comparable for persons of different ages.[8] Although this study is restricted to persons ages 25–54, one might suspect that age differences account, to some degree, for the male/female differences in Tables 1 and 2. However, the age distributions of the male and female respondents were quite similar, the means for the married persons being 38.4 and 37.8 years respectively for the males and females and the standard deviations being 8.7 and 8.6 years. Furthermore, holding age constant produced partial correlations between father's occupational prestige and family income of .132 for males and .256 for females—obviously very similar to the zero-order correlations.

Still another reason for reservations about the validity of the male/female comparisons is a possible sex difference in the accuracy of reports of income. Several studies (e.g., Ballweg, 1969; Ferber, 1955) have indicated that there may be such a difference and that the reports of males may be the more accurate. If so, however, and if the errors in reporting are random, or nearly so, the effects on the results of this study would be to depress the female correlations relative to the male ones (Blalock, 1972:413–5) and, thus, to lower the measured male/female differences. In fact, any sex differences in the accuracy of reporting family income appear to have been largely random, because the distributions of reported family income were nearly the same for males and females, as they must have been in the population.[9] For instance, the means were $16,459 and $16,607 for males and females, respectively, and the standard deviations were $7,540 and $7,698. Thus, it is highly unlikely that male/female differences in the accuracy of reporting family income account to any important degree for the male/female differences found by this study.

CONCLUSION

We believe that the data reported here make very clear the prematurity of the conclusion that "the status structure in the United States is substantially more fluid" when both sexes are taken into account than it appears to be when males alone are considered. In fact, the results of this study suggest that the opposite may well be true. We cannot be sure, of course, since we have not measured all aspects of the status of origin or the status of destination of either males or females (nor is anyone else likely to devise a meaningful summary measure of all aspects of the intergenerational transmission of status).

In any event, it is important if, as the data strongly suggest, there has been greater intergenerational transmission of major dimensions of economic status among females than among males; research is needed to investigate the causes and consequences of that difference.

[8] A finding not directly relevant to the purpose of this study but which has implications for the "double standard of aging" (Sontag, 1972) is that, among the married respondents (1973–1977 file), the correlation of age with family income was .284 for men but only .128 for women. This difference must have resulted from the marriage of a good many younger women to affluent older men and/or from the marriage of a good many of the older women to retired men.

[9] Of course, the distributions of family income were identical in the total populations of married men and women, and they had to be quite similar among whites in the age range of 25–54.

THE IMPACT OF OUTLIERS ON INCOME INEQUALITY*

(COMMENT ON HEWITT, ASR JUNE, 1977; STACK, ASR FEBRUARY, 1979; AND HEWITT, ASR FEBRUARY, 1979)

Hewitt (1977) claimed to have found support for Lenski's (1966:313–25) argument that, within industrial societies, strong socialist parties have effected a considerable redistribution of income in favor of the "lower classes." At the same time, he was unable to find any support for the argument that political democracy, more broadly conceived, has a nonspurious effect on income inequality. More recently, however, Stack has alleged that "an operationalization of political democracy which stresses political participation, as opposed to the structural elements of democracy, is a better predictor of the level of income inequality than social democracy as measured by socialist party strength" (Stack, 1979:171). Hewitt's response is that, despite some problems, Stack's "main point is a good one" and his result "interesting," although Hewitt believes that the issue is complicated, given "the high intercorrelations between the political variables" (Hewitt, 1979:172). As I shall show here, both of these authors' claims are unwarranted, as were the claims concerning the effects of socialist party strength which Hewitt advanced in his original paper.

Stack criticizes Hewitt for placing insufficient emphasis on rates of political participation in his analysis—a reasonable point, given the concern with participation in Lenski's theory. Stack's (1979:170) point—about the need to measure the "overall degree of income differences" rather than to focus solely on income received by the most wealthy—is also reasonable, as Lenski and others were concerned with redistribution from the most wealthy to the least wealthy (the lower classes). Less reasonable is Stack's assertion that, once these two issues are taken into account, participation has a major effect on inequality while socialist party strength does not.

ANALYSIS

Following the suggestion of Stack and others, my measure of income inequality focuses on both ends of the income distribution. Specifically, I use the ratio of the share of income received by the most wealthy population quintile to the share received by the poorest 40% of the population. This measure has three desirable properties. First, it is readily interpretable (and higher scores imply more inequality). Second, it responds to Lenski's concern with both the top *and* bottom ends of the income distribution (in contrast to measures that refer only to the most wealthy). At the same time, the denominator includes the poorest *two* population quintiles in order to capture Lenski's discussion of the lower classes in a way that is not too restrictive. Third, and finally, this measure is more responsive to differences in each end of the distribution—in contrast to the more commonly used Gini ratio, which is most sensitive to differences in the middle range (cf. Allison, 1978:869). However, I should emphasize that the results I report here are not unique to this measure: as interested readers can verify for themselves, similar results are obtained with other ratios, including the Gini ratio.

My data are taken from the same sources that Hewitt and Stack employ.[1] Information on income inequality is drawn from Paukert's (1973) figures, and I adopt the minor modifica-

[1] Hewitt (1977:455) also employs as a second measure of income inequality the spread of earnings between high- and low-paid workers. Unfortunately, as Hewitt acknowledges, this measure completely ignores unearned income and therefore understates the degree of inequality. I therefore do not employ it in the following analysis (note also that it is not discussed in the Stack–Hewitt exchange). However, given that this is the only measure he uses that begins to address both ends of the income distribution, it is especially interesting to observe that even Hewitt's (1977:461–2) results show neither socialist party nor democratic performance effects on the spread of earnings.

Table 1. Regressions of the Ratio of Income Received by the Wealthiest Population Quintile to That Received by the Poorest Two Quintiles on Socialist Strength, Turnout, and Energy Consumption Per Capita

tions suggested by Atkinson (1975:248). Socialist party strength is measured in terms of socialist legislative presence, 1945–65, as reported by Hewitt (1977:459). Figures on turnout (the proportion of the adult population voting) are from Taylor and Hudson (1972:54–6), except for three countries for which information comes from Russett et al. (1964:84–5). Finally, like Hewitt and Stack, I take data on energy consumption per capita from Taylor and Hudson's data set. However, since the income inequality data are for circa 1962, I take energy consumption figures for 1960, rather than 1965, as reported in ICPR (1971).

The top row of Table 1 reports a set of estimates similar to those reported by Stack (1979:Table 1), and based on the same 18 countries that both he and Hewitt analyzed.[2] Consistent with his results, the estimates for turnout and energy consumption per capita are both of the expected sign and have t-ratios greater than 2.0. In addition, the estimate for socialist party strength is smaller than its standard error. Hewitt (1979) suggests, however, that this may not resolve the issue due to the "intercorrelation" between the "political variables" (the relevant correlation, noted by Stack, is .59). To pursue this question, the second and third rows of Table 1 report the effects of the political variables separately, net of energy consumption rates. These figures suggest that Hewitt's complaint may have some basis, in the sense that the t-ratio for socialist party strength in the second row is 1.96. Offsetting this is the fact that the equation as a whole accounts for only 13% of the variance, and has an F-ratio that is not statistically significant at even the .10 level. In contrast, the estimates in the third row appear to provide stronger support for Stack's claim, since the coefficient for turnout has a t-ratio of 5.84, while the equation as a whole accounts for two-thirds of the variance in income inequality and has a high F-ratio.

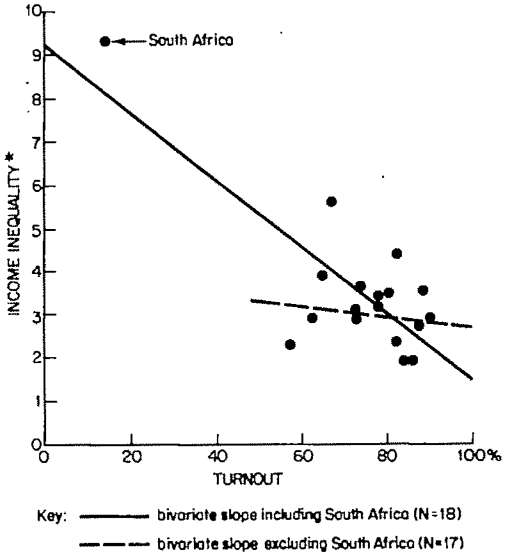
And there the matter would seem to rest. Turnout has a pronounced effect on inequality, while the impact of socialist party strength is marginal. However, it is generally advisable to examine the scatterplots that give rise to estimates such as these, especially when the number of cases analyzed is small (cf. Blalock, 1972:381–3; Anscombe, 1973; Tufte, 1974). Accordingly, Figure 1 arrays income inequality (as defined here) against turnout. Not the least interesting feature of this graph is the presence of an outlier in the northwest corner. Common sense suggests that a check of the robustness of the results reported in the first three rows of Table 1 is warranted. Clearly, we should not rely too heavily on these estimates unless we are sure that they are not a function solely of the inclusion of this single outlier in the analysis.

---

[2] Some readers may think that, as Hewitt (1977:Tables 4–6) does not identify the number of cases analyzed, his analysis of Paukert's data is based on the 25 countries listed in his Tables 2 and 3. This is not, however, the case.

That my results are not identical to Stack's is attributable to two factors. First, my measure of income inequality is slightly different (although, as I have already noted, I obtain the same pattern with Gini ratios in the analyses which follow). Second, both Hewitt and Stack use energy-consumption data for 1965 (I use data for 1960), despite the fact that the data for income inequality are for circa 1962. The sole reason for my focus on the same 18 countries examined by Hewitt and Stack is to maximize the comparability of my results with theirs. I should point out, however, that the inequality data for one of these countries (Italy) are for 1948, which predates the independent variables by a huge margin. Hewitt and Stack blithely ignore this problem, but note that my results below do not depend on the inclusion of Italy in my analysis. Finally, Hewitt's (1977:fn. 1) definition of "modern industrial" identifies the wealth of countries but not the source of that wealth, and is therefore too inclusive (Kuwait in 1965, for example, was not an industrial country!). For a modified definition, see Jackman (1980).

Such a check is particularly important in view of the fact that the outlier is not just any country, but represents the scores for South Africa. Indeed, South Africa does not appear on Lenski's (1966:318–9) list of industrial democracies, for fairly obvious reasons (e.g., nonwhites, an overwhelming majority of the population, do not enjoy basic political rights including the right to vote). Hewitt's (1977:451) original inclusion of South Africa is thus odd, given his claim to be testing Lenski's argument, and given his conclusion, "Strong socialist parties *acting within a democratic framework* appear to have reduced income inequality in industrial societies" (Hewitt, 1977:460, italics added). The location of South Africa within Hewitt's "democratic framework" is certainly questionable, to put it mildly. Stack's inclusion of South Africa is also dubious, as Hewitt (1979:fn. 2) almost notices: the turnout score for South Africa is only 14.3%, which is one quarter the size of the next to lowest figure, and which is three and a half standard deviations below the overall mean turnout figure of 73% for these 18 countries. Looking at the problem another way, the original standard deviation for turnout of 17.4 (when all 18 cases are included) drops to 9.7 when South Africa is excluded (a reduction of 45%). Similarly, the standard deviation for income inequality of 1.7 (N = 18) drops to 0.9 when South Africa is excluded (a reduction of 47%).



*Income inequality is defined as the ratio of income received by the wealthiest population quintile to that received by the poorest 40 percent of the population.

Figure 1. South Africa as an Outlier.

In short, from Figure 1 we learn that there is an extreme outlier in the analysis and that this outlier is having a pronounced effect on the distributions of both the dependent and independent variables. That the case involved is South Africa is of particular interest, given the very restricted political participation in that country. The centrality of race to South African politics makes those politics qualitatively different from the political patterns that prevail in Western industrial democracies.

Accordingly, the bottom three rows of Table 1 repeat the analyses reported in the top half of the table, but with South Africa excluded. The most obvious point here is that excluding just one outlier from the analysis has a dramatic effect on the results. Compare the first and fourth rows of the table. The coefficient for turnout is reduced to one-third its former size; the corrected coefficient of determination plummets from .647 to .027; and the overall F-ratio drops from 11.41 to 1.15. Note that the t-ratio for turnout also drops from 4.79 to less than 1.00. These are drastic changes that indicate that Stack's results can be attributed solely to the inclusion of South Africa in the analysis. (To illustrate these changes graphically, I have drawn the two bivariate slopes in Figure 1.) Indeed, these changes represent a textbook example of the problems that outliers can create. The similarity between Figure 1 and graphs that are explicitly and solely constructed to illustrate the pitfalls of outliers is striking: compare Figure 1 with either Figure 17.10a in Blalock (1972:382) or the top part of Figure 3.18 in Tufte (1974:107).

The fifth row of Table 1 shows that Hewitt's original analysis suffers from the same problem.The coefficient for socialist party strength in this row shrinks to 40% of the size of the corresponding estimate in the second row, and is barely larger than its standard error.[3] The figures in the fifth row also underscore the irrelevance of Hewitt's (1979:172) remark about the possible confounding effects of the correlation between turnout and socialist strength.[4] Finally, the estimates in the bottom row of the table show that, even when socialist strength is excluded from the equation, the outlier effect remains dominant: the F-ratio is less than 2.0 and the $\overline{R}^2$ is .083, while the coefficient for turnout drops to 40% of its original size (and its t-ratio falls from 5.84 to 1.45).

---

[3] While the outlier issue is a severe problem for

CONCLUSIONS

The foregoing analysis clearly demonstrates that there is no justification for any of the conclusions advanced by Stack (1979) and Hewitt (1979). It also suggests that there is little reason to have any confidence in Hewitt's original conclusion. In other words, this analysis is consistent with results reported earlier by Parkin (1971) and Jackman (1975): neither electoral participation nor socialist party strength affects the overall degree of income inequality.

Hewitt's (1977) analysis, it is even more crippling for Stack's (1979). This is because in Hewitt's case South Africa represents an extreme score on the dependent variable only, whereas in the Stack case it has extreme scores on both the dependent *and* independent variables.

[4] Elsewhere, I have shown—with these and with more recent and comparable data on income inequality—that socialist parties have not had a marked effect on income inequality. To the extent that they have had any egalitarian effect, their impact has been minimal and has favored middle-income groups, never the least wealthy (i.e., never the poorest 40% of the population), despite the support that these movements receive from this sector (Jackman, 1980).

REPLY TO JACKMAN*

Jackman is able to conclude that Socialism does not affect income inequality because his analysis differs from mine in two respects: first, he examines a different set of countries; second, he uses a different measure of equality.

I agree that its racial situation may make South Africa a special case.[1] I am therefore including a reanalysis omitting South Africa but retaining my original measures.

The results show clearly that even without

South Africa (that is, with only 18 cases) Socialist Party strength is still significantly associated with a reduction in the share of the top income categories. If additional cases are added, the correlations are higher and more significant.[2] From examination of the scattergrams it is apparent that no outliers are producing these results.

The crux of the disagreement between Jackman and myself does not concern whether or not South Africa is an outlier, but how income inequality should be measured.

Jackman criticizes the measures I used (shares of top 5% and top 20%) and suggests that a measure which captures "the overall degree of income inequality" or "redistribution from the most to the least wealthy" is preferable. I agreee that Socialist governments are expected not only to take from the rich (as I have shown they do), but also to give to the poor. However, we must consider three questions in selecting an appropriate measure: What government policies affect income distribution? At what stage in the policy process is income inequality measured? What is the relation between "class" and income category?

Government policies affect income distribution in three ways:

(1) They alter market forces through monetary policies, affecting employment, inflation and interest rates, or through direct controls.[3]

(2) They tax households both directly and indirectly.

(3) They increase household resources either through direct transfer payments or by providing free or subsidized goods and services.

Since Paukert's (1973) figures are of the distribution of income before tax, they take into account, of course, *only* the effect of the first set of policies plus transfer payments. If we consider income "after tax," the distribution will be more equal; and if we calculate the distribution after the allocation of government goods and services, it will be still more equal. Thus, according to Nicholson's study cited by Atkinson (1975), the Gini coefficient for pretax income in Britain in 1970 was 0.28, but 0.20 after all taxes and benefits were taken into account.

I would argue that interference with the allocation processes of the market economy under Socialist governments will reduce the incomes of rentiers, business and certain professions (for example, physicians). Since such "classes" in the Weberian sense are largely contained within, and equivalent to, the top quintile of income recipients, the decline in this category's share is thereby explained. The lowest quintiles do not gain substantially at this stage because many individuals and households are outside the work force and, hence, unaffected by government economic policies.[4]

---

[2] The additional cases are the next five most highly developed countries listed in Paukert (1973): Greece, Panama, Mexico, Chile and Jamaica.

[3] To take a striking example, physicians in the United States receive the incomes they do because they are able to exploit their market position to its maximum. In the United Kingdom socialized medicine allows the State, as the only effective purchaser of their services, to hold physicians' incomes at a much lower level. Rent control and minimum wage legislation are other examples.

[4] The question of the occupational composition and labor-force status of the income categories needs more study. I am relying upon a chart, *Social Stratification in the U.S.*, which shows that in 1978, managers, self-employed, and professionals constituted more than half of those in the top 20%, while more than two-thirds of these occupations fall into the top quintile. The chart also shows that in the bottom quintile a majority of units had no one in the labor force.

Redistribution to the poor is conventionally assumed to occur through a combination of progressive taxation and welfare state expenditures.[5] Therefore it is necessary, when only pretax figures are available, to make a separate estimate of the redistributive effect of taxation and social service expenditures. I did so in my original study and found that the greatest amount of redistribution occurred in polities with strong Socialist Parties.

I think it probable that Jackman's finding that the poor are not helped by Socialism is explained by the fact that his measure is of inequality before the impact of taxation and social service expenditures.[6] I look forward to reading his forthcoming, more detailed, analysis.

[5] According to the *Washington Post* (September 12, 1979:21), in Sweden "maintaining the welfare state costs citizens over half their total earnings in national and local taxes, with many above-average wage earners paying much more than that. Swedes, especially those with below-average incomes, receive a lot back in . . . benefits."

[6] It should be noted that in a ratio measure such as Jackman now proposes, the effect of taxation is even more marked than with Gini values. In the United Kingdom in 1967 the top 10% received 28.0% of pretax income while the bottom 30% received 10.4%. The posttax figures were 24.3% and 12.0%, which means that the ratio of top to bottom is 2.7 before tax but only 2.0 after tax (Atkinson, 1975).

IN DEFENSE OF MICROECONOMIC THEORY*

(COMMENT ON COOK AND EMERSON, ASR, OCTOBER, 1978)

In their recent article, "Power, Equity and Commitment in Exchange Networks," Cook and Emerson claim to expand exchange theory through the use of exchange networks. In addition, they argue that their formulation solves two problems that economic theory has not solved: (1) the problem of indeterminacy in the economic study of exchange, and (2) the problem of incorporating the concept of commitment. More specifically, they contend that

> conventional microeconomic theory leaves two-person interaction indeterminate because it is a theory organized around *individual decision making* in an asocial *market* composed of many traders. But when only two parties engage one another in reciprocally tactical interaction, be they husband or wife or organized labor and management, the market mechanism is replaced by *social interaction* and economic theory is left with little to say about the outcome. (Cook and Emerson, 1978:722, emphasis in the original)

We agree that their formulation does seem to advance important notions involved in sociological exchange and equity theory. However, we do not agree that their formulation solves problems heretofore unsolvable by microeconomic exchange theory. This point of contention between ourselves and the authors is an important one: How such a disagreement is resolved will affect the direction of future exchange formulations.[1] If Cook and Emerson are correct in their analysis, then we should more fully develop those concepts suggested by their formulation and disregard economic theory for the study of social relations. If Cook and Emerson are incorrect in their analysis, then we should try to adapt those economic concepts that fit our sociological interests.

[1] Cook and Emerson (1978:721–2) are aware of the importance in distinguishing economic exchange from social exchange and, in fact, emphasize the importance of the distinction:

> There is in Economics a well developed science of exchange. Therefore, if "social" exchange theorists are going to build another science of exchange, it is incumbent upon them to relate their work to economic theory, attending to and highlighting important differences.

The Problem of Indeterminacy in the Economic Study of Exchange

The authors contend that microeconomic theory is indeterminate for predicting exchange outcomes for bilateral monopoly. We believe their contention to be an unfair oversimplification. If the only information available is the indifference curves for actors, it is true that microeconomic theory is indeterminate in its predictions. However, if further theoretical assumptions concerning the nature of the interaction are imposed, the predictions of microeconomic theory are no longer indeterminate. There are numerous rules or norms that can function as constraints upon two-person interactions. If these constraints are given appropriate mathematical expression they allow microeconomic theory to predict the results of two-person interactions.

Coddington (1968) discusses constraints that may be imposed and demonstrates that the outcomes of bilateral monopoly are not necessarily indeterminate. For example, Coddington develops a microeconomic model to predict bargaining outcomes. A series of mathematical constraints are imposed upon the indifference curves for two actors engaged in a bargaining process. These constraints include assumptions concerning the form of actors' bargaining expectations, actors' behavioral adjustment concerning bargaining decisions, and the consistency of actors' decisions over time. The imposition of such constraints allows for the exact prediction of bargaining outcomes in bilateral monopoly.

Thus, it is incorrect to contend that microeconomic theory is indeterminate in its ability to predict the outcomes of two-actor interaction. By imposing mathematical constraints, Coddington (1968), Bowley (1928), and others have provided theoretical solutions to the problem of indeterminacy. When Cook and Emerson state that the microeconomic theory is indeterminate, it is analogous to our stating that social power theory is indeterminate when the equity assumption is not specified. It is not that either theory is indeterminate—it is that both theories require additional theoretical constraints to predict the outcomes of two-actor interactions.[2]

The "Asocial" Market, Rationality, and Commitment

Cook and Emerson maintain that microeconomic theory cannot deal with social interaction because the market concept is "asocial." Their assumption is that microeconomic theory is restricted to the analysis of individuals' decisions regarding material goods. Contrary to their assumption, the market concept in economics may consist of all variables that might affect an actor's decision. Such variables often include material goods and money. However, the market may also include nonmaterial variables such as social approval, status, and respect. Several economists using the concept of market have developed theories about such "noneconomic" behaviors as marriage and child-rearing (Becker, 1973; 1974a; and 1974b); charity (Schwartz, 1970); and suicide (Hamermesh and Soss, 1974). Gramm (1975), for example, formulates a theory in which she assumes that the household derives utility from various commodities. One of the commodities she considers is "childness"—a good which takes time and children to produce. Childness seems an excellent example of a good that is both nonmaterial and directly related to social interaction.

The misconception that economics deals only with material goods in an asocial market may stem from the emphasis placed upon the concept of price. However, price is simply a measure of scarcity and, as such, may have nothing at all to do with material goods and money. In fact, we suggest that the notion of price (what must be given up to obtain an additional unit of a good) is an excellent measure of commitment and has been used in microeconomics in precisely the way in which Cook and Emerson wish to use it. For example, the theoretical measure of the commitment of actor A to actor B is the alternatives A is willing to forgo in order to maintain interaction with B.

The fact that economics deals with rational actors is another reason that Cook and Emerson believe economics cannot deal with social commitment. They believe that the concept of rationality implies that actors seek only to maximize their individual gains, irrespective of other actors. Thus, "exchange partners develop no loyalties or longitudinal commitments to one another (Cook and Emerson, 1978:728)." However, the requirement of rationality is not a dictate about how people act. Rather, it is a heuristic tool for the construction of theories. The notion of rationality can be translated into "consistency." For example, economic theory demands that if an actor made a certain choice under a given set of conditions at one point in time, he or she will make the same choice under exactly the same conditions at subsequent points in time. The choice itself may be considered "irrational" by common standards—for example, the actor may choose to date a man who beats her rather than date another man—but the choice is considered "rational" within the economic framework, if it is consistent over time. Thus, Cook and Emerson are incorrect in their conclusion that the assumption of rationality in economic theory precludes the study of social interactions involving commitments between actors.

---

[2] In the Cook and Emerson formulation, the additional constraint is the equity assumption. In the Coddington formulation, the constraints are several mathematical functions.

We are not saying that the Cook and Emerson article is unimportant. We think it is very important. However, should social power and equity researchers abandon the use of economic theory, as Cook and Emerson would have us do, we feel a serious mistake will be made. It is not that microeconomic theory is fully developed for all our interests (it is not) but, rather, that some of its concepts can yield great theoretical flexibility for sociological theory.

DOES MICROECONOMIC THEORY NEED A DEFENSE?

(A REPLY TO MARTIN AND SELL)*

Martin and Sell in their comment on "Power, Equity and Commitment in Exchange Networks" take issue with our treatment of microeconomic theory. They make two basic claims, that: (1) our formulation (while it does "advance important notions involved in sociological exchange theory and equity theory") does not "solve problems heretofore unsolvable by microeconomic theory"; and (2) we imply that "economic theory should be disregarded." Before dealing with the specific issue of indeterminacy in a bilateral monopoly, let us deal with their second claim.

Should exchange theorists "abandon" economic theory? Our discussion of bilateral monopoly was included in order to clarify how our work articulates with and builds upon economic conceptions of exchange. We believe Martin and Sell's claims (1) that we imply in our analysis "economic theory should be disregarded" and (2) that power and equity researchers should "abandon the use of economic theory" are gross misrepresentations of our position. In our article we state: "There is in Economics a well developed science of exchange. Therefore, if 'social' exchange theorists are going to build another science of exchange, it is incumbent upon them *to relate their work to economic theory*" (Cook and Emerson, 1978: 721–2, fn. 3; emphasis added). Our article represents our attempt to relate the two bodies of theory and to develop further social exchange theory grounded upon economic theory.

Is microeconomic theory indeterminate in the case of bilateral monopoly? Martin and Sell also take issue with our statement that "conventional microeconomic theory is indeterminate" in regard to the outcomes of exchanges in a bilateral monopoly. They argue that economic theory is not indeterminate in this case. Many economists would disagree with Martin and Sell. For example, Fellner (1959:10) concludes: "after the establishment of a range of possible values, a *different apparatus* (i.e., something other than economic theory) should be employed in the discussion of what is likely to happen within that range" (emphasis added). That "different apparatus" in our article is social exchange theory.

Essentially, Martin and Sell argue that microeconomic theory can solve the problem of indeterminacy in a bilateral monopoly by including additional assumptions and variables in the theory, such as information on bargaining expectations, bargaining skill, consistency in decision making, and so forth. That the incorporation of additional information (either sociological variables or extra assumptions) resolves the indeterminacy problem is hardly surprising to either sociologists or economists.[1] Coddington (1968:11) agrees with us on this point: "The existence of indeterminacy seems to imply that we cannot achieve a proper understanding of bilateral monopoly without introducing further concepts into the theoretical framework." This is precisely the point we make in our article; if additional assumptions regarding power and equity are specified for two-party exchanges, the problem of indeterminacy is resolved. That is, *with the addition of assumptions* based upon power-dependence theory and equity theory within sociology, derivations can be made regarding the exchange outcomes in what economists refer to as a bilateral monopoly.

[1] If we are satisfied with making an arbitrary set of

Economists Ferguson and Gould (1975:288) state that "the information the economist has is not sufficient to determine the precise market solution . . . the solution is based on bargaining skills and other personal characteristics *anterior* to the realm of economic analysis" (emphasis added). What is defined by some economists as "anterior" to the realm of economics has in fact been the subject of *extensive* examination within sociology (i.e., social exchange theory, bargaining theory within social psychology, power-dependence theory and equity theory). That economists like Becker (1974) have recently "rediscovered" social interaction is a credit to the field of economics. As Becker (1974:1091) explains it:

> Probably the main explanation for the neglect of social interaction by economists . . . [is due to] excessive attention to formal developments during the last 70 years. As a consequence, even concepts considered to be important by earlier economists, such as social interactions, have been shunted aside.

Economic vs. Social Exchange Theory

Concerning the scope of economic and social exchange theory, Martin and Sell fail to make a distinction between theory and concrete reality or between analytical distinctions and concrete differences. As Cook (1979) points out in her discussion of social vs. economic exchange theory, economists and sociologists tend to use different theoretical assumptions in their analysis of the same phenomenon. The difference resides in the nature of the theories being applied and not in the object of study. For example, economists tend to focus upon single transactions, *abstracted* to a large degree from the social context in which they occur in order to arrive at empirical estimates of important parameters such as price. Economic actors are typically buyers and sellers isolated in theory (i.e., the perfectly competitive market) from organizational contexts and continuing social relations. In contrast, social exchange theory, as formulated by Emerson (1972a; 1972b) and others, treats the exchange relation as the primary unit of analysis, where the exchange relation is defined *as a series of interrelated transactions over time.* Thus sociological theory focuses upon relatively enduring exchange relations among actors which lead to other social processes of theoretical interest (e.g., for Blau, 1964, social differentiation among exchange partners; or for Malinowski, 1922 and Ekeh, 1974, social solidarity and societal integration). The emphasis upon enduring social relations led us to extend social exchange theory beyond the dyad to exchange networks in order to allow for the analysis of exchange principles in networks of social relations. Martin and Sell seem to have overlooked completely the primary purpose and the empirical work reported in our article which analyzes four-party exchange networks, not dyadic exchanges.

The "Asocial" Market, Rationality and Commitment

Martin and Sell infer an erroneous conclusion from the following statement in our article: "Conventional microeconomic theory . . . is a theory organized around individual decision making in an *asocial* market composed of many traders."

They infer that we believe economic theory is restricted to the analysis of material goods. Nowhere in the article do we make this claim. Martin and Sell equate asocial with material goods; we do not. In fact, as Cook (1979) has argued, the primary distinction between economic theory and social exchange theory does not reside in the nature of the actors (i.e., rational or not), the nature of the resources (material or social), or the nature of the markets (perfect vs. imperfect) involved. Further, as Emerson (1976; 1980) and Cook (1979) have argued, the issue of the "rational actor" is fundamentally a question of the psychology of the actors involved and is not a question often dealt with empirically by either economists or sociologists. The notion is usually included in the theory as a "simplifying assumption," as Martin and Sell correctly point out. Emerson's (1972a; 1972b; 1976; 1980) position that the ex-

---

assumptions, as Bowley (1928) did, we can easily resolve the indeterminacy. For example, if we assume that one party can determine both price and quantity (Why not assume this?), of course there's no indeterminacy. What we aim to do, however, is not to select arbitrarily a set of assumptions that are enough to solve the problem but to test the validity of these assumptions and to specify the conditions under which these assumptions hold.

change relation should be the *primary unit of analysis* implies that "rationality" can be treated as a variable attribute of exchange relations or exchange structures and not as an assumption about individual motives. From this perspective, motives, per se, become ancillary to the theory, and debates concerning the motives of the exchange participants are not that informative. Describing consistency in behavior over time as "rational" does not help explain the consistency at all; nor does assuming that people behave consistently over time explain why people do so. Our research attempts to specify the conditions under which exchange actors will behave consistently in one fashion or another regardless of whether we refer to their behavior patterns as rational or not. Our experiment is an attempt to specify empirically the conditions under which power is exercised and commitments emerge within exchange networks. The network structure (degree of power imbalance) can be viewed as an important determinant of the extent to which commitments emerge between exchange partners (regardless of whether or not we view such commitments as "rational" or "irrational").

ITEMS

■ JAMES C. CRAMER (Fertility and Female Employment) is Assistant Professor in the Sociology Department and Graduate Group in Ecology, University of California at Davis. His current work also includes (a) continuing research on female employment and fertility; and (b) population growth, social impact assessment, and environmental policy analysis.

■ LARRY ISAAC (Political Protest Orientations among Blacks and Whites) is Assistant Professor in the Department of Sociology at Florida State University. He is involved in research which focuses on the determinants of State activity and its relationship to macroeconomic and distributional outcomes. ELIZABETH MUTRAN is a Research Associate, at Duke University, on a National Institute of Mental Health (NIMH) grant, working on the topic, "The Multidimensional Aspects of Widowhood." Her current research extends her interest in socialization experiences within the family context, now primarily focused on the postparental stage. SHELDON STRYKER is Professor in the Department of Sociology and Director, Postdoctoral Training Program in Social Psychology at Indiana University. His book, *Symbolic Interactionism: A Social Structural Version*, is forthcoming from Benjamin/Cummings, Menlo Park. His present research is toward relating commitment, identity salience and role performance.

■ BARBARA LASLETT (Place of Theory in Quantitative Historical Research) is Associate Professor in the Department of Sociology at the University of Southern California. The subject of social change and the family in Los Angeles, California, between 1850 and 1900, occupies her present research.

■ ALAN J. LIZOTTE is Assistant Professor in the Department of Sociology at Emory University. His current research centers on patterns of firearms ownership and use in Illinois, at both the county and individual levels. He is also studying weapon specific homicide trends in Atlanta, Georgia. DAVID J. BORDUA is Professor in the Department of Sociology at the University of Illinois, Urbana-Champaign. He continues his studies of firearms ownership and public policy. With Lizotte, Gary Kleck, and Van Cagle, he coauthored *Patterns of Firearms Ownership, Use and Regulation in Illinois*, Vol. XVIII, a report to the Illinois Law Enforcement Commission.

■ WILLIAM C. RAU (The Tacit Conventions of the Modernity School) is a Visiting Assistant Professor in the Department of Sociology at the State University of New York at Albany. Currently, his research focuses on (1) the development of a structural theory of psychological modernity, (2) clarification of problems in the comparative analysis of value systems, and (3) empirical exploration of the "industrial man" hypothesis in convergence theory.

■ DENNIS P. HOGAN (The Transition to Adulthood as a Career Contingency) is a Faculty Research Associate in the Population Research Center and Assistant Professor in the Department of Sociology, both at the University of Chicago. His book, *Fertility and Family Planning in Rural Northern Thailand*, coauthored with Somphong Shevasunt, is forthcoming from the University of Chicago Community and Family Study Center. He is engaged in further research on the life-course transitions of 20th-Century American males, teenage fertility in Chicago, and fertility levels and trends in southeast Asia.

■ SURESH L. KONDA (An Opportunity Labor Demand Model) is a Ph.D. candidate at Carnegie-Mellon University, where he is researching system models of mobility—incorporating decision-making into stochastic models. SHELBY STEWMAN is Associate Professor in the School of Urban and Public Affairs at Carnegie-Mellon University. His research involves: (1) aging and organizations; (2) longitudinal analysis of the United States Government labor force; (3) development of a methodology for projecting labor demand of construction workers, by craft, in metropolitan areas; and (4) the use of survey methods to examine cognitive processes. . . .

■ CAROL H. WEISS (Truth Tests and Utility Tests) is a Senior Research Associate in the Graduate School of Education, Harvard University. She has two books forthcoming: *Social Science Research and Decision Making* (with M. J. Bucuvalas), from Columbia University Press; and *Making Bureaucracies Work* (with A. H. Barton), from Sage. She is currently conducting a longitudinal study of opinion and practice in the alcoholism treatment field and the extent to which they reflect recent research results. MICHAEL J. BUCUVALAS is a Senior Analyst in the public affairs division of Louis Harris and Associates. There, he is doing survey research on a variety of issues—Vietnam-era veterans, conservation of natural resources, family violence, solar energy applications, and public utility management. He coauthored (with Weiss) the book, *Social Science Research and Decision Making*.

■ DAVID A. McGRANAHAN (The Spatial Structure of Rural Income Distribution) is a Ph.D. candidate in the Department of Rural Sociology, at the University of Wisconsin, Madison. His current research focuses on small-community and regional development as affected by the spatial organization of class and other interests.

■ PAUL ATTEWELL (Comment on Robinson and Kelley) is Assistant Professor, University of California at Santa Cruz, as well as a Postdoctoral Research Fellow at The Institute for the Study of Social Change, University of California at Berkeley. His work presently is in researching economic sociology and complex organizations. ROBERT FITZGERALD is a Ph.D. candidate in the Department of Sociology, also at the University of California at Berkeley. He and Attewell are currently examining various aspects of Marxist stratification theory. He recently completed a study on the proneness of juries to convict when persons opposed to the death penalty were excluded from juries.

■ JOHN BRAITHWAITE (Comment on Gottfredson and Hindelang) is a Criminologist with the Australian Institute of Criminology and is currently researching transnational corporate crime. In press, at the Institute, is his forthcoming book, *Prisons, Education and Work: Towards a National Employment Strategy for Prisoners*, DAVID BILES is Assistant Director of Research at the Australian Institute of Criminology, presently working on the topic of classification of prisoners. His book, *The Management of Long-Term Prisoners in Australia*, written with Grant Wardlaw, is forthcoming.

■ NORVAL D. GLENN (Comment on Glenn, Ross, and Tully) is Professor in the Department of Sociology, at the University of Texas at Austin. His current research deals primarily with (a) aging and attitudinal stability, (b) the noneconomic utility of formal education, and (c) the effects of children on the psychological well-being of parents. SANDRA L. ALBRECHT is Assistant Professor, Department of Sociology, University of Kansas, and her research presently centers on participatory democracy (comparative), social stratification, and the sociology of work.

■ ROBERT W. JACKMAN (Comment on Hewitt, on Stack, and on Hewitt) is Associate Professor of Political Science, Michigan State University. He is doing research on (1) Coups d'etat and related forms of political violence in Third World countries, and (2) the nature of social class identification in the United States.

■ MICHAEL W. MARTIN (Comment on Cook and Emerson) is Assistant Professor, Department of Sociology, at Trinity University, San Antonio, and is also doing research on the factors affecting individuals' choices of equity norms. JANE SELL is Assistant Professor, Department of Sociology, Texas A & M University. She is currently researching the mathematical definition and empirical estimation of reinforcements with varying strengths.

New from Pittsburgh

THEORETICAL METHODS IN SOCIOLOGY: SEVEN ESSAYS **$19.95s**
Lee Freese, Editor
"I shouldn't be surprised if this book becomes the authoritative source for sociologists on axiomatic theorizing. Certainly it clears away several prevalent misconceptions."
—Robert W. Avery

In analyzing various theoretical methods and issues, Freese and his colleagues imply that a cumulative science of sociology would have to ask different kinds of questions than those which typically guide sociological research.

FEMALE AND MALE IN LATIN AMERICA: ESSAYS ***NOW IN PAPERBACK*** **$6.95s**
Ann Pescatello, Editor

This pioneering study of Latin American women is based on current disciplinary methodologies and original field research undertaken by historians, anthropologists, sociologists, demographers, psychologists, political scientists, and literary critics.

ORGANIZATION STUDIES

An international multidisciplinary journal devoted to the study of organizations, organization, organizing and the organized in, of and between societies

A New Quarterly

Organization Studies aims to provide a more internationally based forum than has previously existed for ideas and research, and for the exchange of personal experiences, in the study of organization and the organized. The scope of Organization Studies will be broadly rather than narrowly conceived across the diversity of social science approaches and paradigms. It will range from the theoretical, even the speculative, to relevant contemporary problems and empirical research reports.

TRADITION and *INNOVATION* for 1980

Focus on Society: An Introduction to Sociology, Second Edition

Norman W. Storer, Bernard M. Baruch College, City University of New York

Comprehensive and penetrating examination of the basic structures and dynamics of society. Clear writing and a carefully-developed presentation of a modified structural/functional perspective provide unity and coherence. In this edition are: new chapters on socialization and changing sex roles, updated "focus" sections on key concepts and ideas, conceptual diagrams, end-of-chapter glossaries, and appendices on the empirical research in the field. Accompanied by an Instructor's Manual with tests.

(07337) 544 pp. paper *Available Now*

Introduction to Social Problems

Leonard Glick and Daniel E. Hebding, both of Community College of Philadelphia

The aim of this well-researched text-reader is to examine the nature and causes of, the interrelationships, and possible solutions to contemporary social problems. Emphasizes the sociological approach to the study of social problems, but also draws on evidence and theory from other fields. Excellent pedagogy includes lists of key terms at chapter-end, margin notes, chapter summaries. Comprehensive Instructor's Manual.

(02600) 544 pp. paper *Available Now*

Gerontology: A Behavioral Science Approach

Richard C. Crandall, Lake Superior State College

Comprehensive and thoroughly documented examination of issues from a variety of perspectives. Includes chapters on the chronological development of gerontology as a science and on the aged in preliterate society. Instructor's Manual with tests.

(01252) c. 496 pp. *Available Now*

The Social Reality of Death: Death in Contemporary America

Kathleen C. Charmaz, California State University at Sonoma

Important new book uses a distinctively sociological approach to integrate the interdisciplinary materials in the field of death and dying.

(01033) 352 pp. paper *Available Now*

Founding Theory of American Sociology 1881-1915

ROSCOE C. HINKLE *Professor of Sociology, Ohio State University, Columbus*

Based on a comparative study of the theories of such sociologists as Ward, Sumner, Giddings, Ross, Small and Cooley, this is a systematic and rigorous analysis of the main features of earlier sociological theory in the US. Professor Hinkle shows that early theory focused on social ontological interests, the pervasive ontological stance being evolutionary naturalism, within which some sociologists adhered to a social evolutionary theory of change while others preferred a social process theory. Contrasting earlier and later theories, the book provides a basis for interpreting one period in American theory in relation to others. *International Library of Sociology* 135.00

The Material Word

Some Theories of Language and its Limits

DAVID SILVERMAN and BRIAN TORODE *Goldsmith's College, London and Trinity College, Dublin*

The Material Word is an exploration of language as a body of practices. Each section begins with an interrogation of an important theory of language (including Wittgenstein, Husserl, ethnomethodology, J.S. Austin, Barthes, Derrida and Foucault). The results are applied to related texts (Althusser, Locke, Bernstein, Labov, Kafka, Robbe-Grillet, and Perrault). $24.50, paper $14.95

The Inheritance of Inequality

LEONARD BROOM, F. LANCASTER JONES, PATRICK McDONNELL and TREVOR WILLIAMS

'This is the most extensive study of stratification and social mobility in the status attainment tradition thus far reported for any national population other than the United States [Australia] ... carefully done and well integrated with current theoretical development.' — *from the Foreword by Professor William H. Sewell of the University of Wisconsin. International Library of Sociology* $27.50

Organization, Class and Control

STEWART CLEGG and DAVID Dunkerley *Griffith University, Brisbane and School of Behavioural and Social Science, Plymouth Polytechnic, England*

This is the most complete book to have appeared on the subject and is likely to become indispensable to all who study organizations. Its major innovation lies in its reconceptualization of organization as control of the labour process in the context of a particular mode of production, that of capitalism. April *International Library of Sociology* $40.00, paper $20.00

The International Yearbook of Organization Studies 1979

EDITED BY DAVID DUNKERLEY and GRAEME SALAMAN

Contributors: Erik Olin Wright, Chilla Bulbeck, Alexander Kouzmin, Gibson Burrell, Paul Goldman, Donald R. Van Houten, D. Eleanor Westney, Craig R. Littler, Peter Singelmann, James L. Price, Allen C. Bluedorn, Meredith Gould, Stephen Mugford

This is the first volume in a series conceived to bring together contemporary developments in the field of organization studies. $37.50

The Ceremonial Order of The Clinic

P. M. STRONG *University of Oxford*

This study of over one thousand American and Scottish paediatric consultations offers a significantly improved account of medical consultation which can be applied to adult as well as child patients. *International Library of Sociology* $20.00

Ideas and Intervention

Social Theory for Practice

JOE BAILEY *Kingston Polytechnic, England*

This book presents a practical view of the importance of social theorizing. It examines social intervention in three areas — law, social work, urban planning — and concludes by proposing a pluralist view of theory as the best strategy for a sociology relevant to practice. $24.00, paper $12.00

Language and Literacy

The Sociolinguistics of Reading and Writing

MICHAEL STUBBS *University of Nottingham*

This book provides a basis for a socio-linguistic theory of literacy. The author believes that a systematic theory of literacy must be based on an understanding of a number of factors, such as the relationship between spoken and written language, the social, educational and technological pressures on written language, and the variability of spoken language and the relative uniformity of written language. *Routledge Education Books* $25.00, paper $12.50

Disclosures To A Stranger

Adolescent Values in an Advanced Industrial Society

TOM KITWOOD *University of Bradford*

The condition known as 'adolescence' is examined in four broad areas: family life, relations with other adolescents, formal and informal work, and the development of 'self-values.' *Social Worlds of Childhood* $32.50

Now in Paperback

Origin and Significance of The Frankfurt School

A Marxist Perspective

PHIL SLATER *The City University, London*

'A tightly written, thoroughly researched and most thoughtful analysis' — Choice

'A significant and worthwhile work.' — Robert Gogel, *Sociology and Sociological Research* *International Library of Sociology* $7.95

Meaning and The Moral Sciences

HILARY PUTNAM *Professor of Philosophy, Harvard University*

'Putnam is an engaging and tantalizing thinker. I suspect that the book will attain a position within philosophy of the social science which will make it required reading for every aspiring methodologist.' — Philip Pettit, *The Times Higher Education Supplement* *International Library of Philosophy* $4.95

Class Structure in the Social Consciousness

Translated from the Polish by Sheila Patterson

STANISLAW OSSOWSKI *Late Professor of Sociology, University of Warsaw*

'It deals with some of the most important problems of our time with a perceptiveness rarely present in comparable Western studies, the results not only of a perspective widened by historical experience, but also of the author's encyclopedic knowledge.' — *Views and Reviews* *International Library of Sociology* $10.50

The Rules of Disorder

PETER MARSH, ELIZABETH ROSSER and ROM HARRÉ

'A most compelling picture of what has previously been the chaos and the din that the media have faithfully portrayed.' — Anthony Clare, *Psychology Today* *Social Worlds of Childhood* March $7.95

Reissues

Revolution in a Chinese Village: Ten Mile Inn

ISOBEL and DAVID CROOK

First published in 1959, this book is a ten years' history of one Chinese village, covering the period immediately before the setting up of the Chinese People's Republic. The authors describe in vivid detail, based on first-hand observation, the social, political and economic changes involved in passing from the landlord regime to land redistribution under Communist rule. *International Library of Sociology* $20.00

The First Years of Yangyi Commune

ISOBEL and DAVID CROOK

'The Cooks of Peking have done a major service in producing this sequel to their earlier *Revolution in a Chinese Village.* It will rank for many years as the best insight yet offered us into the mobilization of one-fifth of humanity into the communes.' — *The Times Literary Supplement* *International Library of Sociology* $22.50

DORSEY

IMPORTANT NEW TITLES

INTERVIEWING: Strategy, Techniques, and Tactics, Third Edition
Raymond L. Gorden, Antioch College
Presents basic concepts relevant to the interviewing process and richly illustrates them with concrete examples. Provides dozens of skill-building activities in the form of critical questions, laboratory problems, and field problems.

EXPERIENCING SOCIAL RESEARCH, Revised Edition
(paperbound)
John F. Runcle, Development Analysis Associates, Inc.
Combination of text and carefully chosen problems, stressing that the student should learn the more theoretical aspects of research methods and then apply what has been learned in solving the problem. Suggestions are given for the method of approach and the analysis of the gathered data.

THE URBAN ENVIRONMENT *(paperbound)*
Samuel E. Wallace, University of Tennessee, Knoxville
Integrates and synthesizes urban theory and research within a comprehensive perspective of ecology. It analyzes the historical past as it structures the present, the present as urbanites live it, and the future as seen in contemporary patterns.

INTRODUCTION TO SOCIAL WELFARE AND SOCIAL WORK: Structure, Function and Process
Beulah R. Compton, University of Minnesota
Introduces students to the development of social welfare, the profession of social work and the issues involved in the development of both the institution and the profession. Kahn's notion of systems of social welfare as an organizing framework for social welfare and a sociological perspective on the professions as the framework for that consideration is used.

THE SOCIAL SYSTEM OF THE PLANET EARTH

by Kenneth B. Boulding, University of Colorado,
Elise Boulding, Dartmouth College, and Guy M. Burgess,
Massachusetts Institute of Technology

Innovative! Engaging! A unique interdisciplinary treatment of the world social system. A science fiction framework postulates the appearance of an extraterrestrial visitor who seeks knowledge of the Earth. Students get involved in organizing a research institute to gather and interpret data on population dynamics, history, religion, science, economics, social stratification, distribution of wealth, the international system, and more for this visitor.

THE HIGHLY ACCLAIMED, HIGHLY REGARDED AND *HIGHLY CONTROVERSIAL* NEW BOOK THAT SETS FORTH A CHALLENGING NEW THEORY OF HUMAN NATURE

"Mary Midgley refutes, in this lively and accessible essay, a host of what she believes are dangerously, sometimes willfully simplified theories about man's nature—on the part of biologists, psychologists and other social scientists, and some of the major philosophers of the past two centuries..."
—*The Atlantic Monthly*

"This is a very important book. Mrs. Midgley is a rare philosopher who has learned enough evolutionary biology to understand its deeper layer of meaning."
—*Iris Murdoch*

BEAST AND MAN
THE ROOTS OF HUMAN NATURE
MARY MIDGLEY

Cutting across many disciplines—psychology, philosophy, ethology, biology, sociology—this is a serious and richly informative new book that deepens our understanding of other species while showing us why we behave the way we do.

Meridian **F529/$5.95**

New American Library Education NAL **1633 Broadway New York 10019**

American National Election Studies Data Sourcebook, 1952–1978

Warren E. Miller, Arthur H. Miller, and Edward J. Schneider

Here, for the first time in book form, is the most basic information describing the recent electorate's partisan loyalties, attitudes on issues, opinions about the American political system, and participation in elections and election campaigns. Anyone with an abiding interest in American national politics will find this invaluable. 456 pp. $25.00

American Social Attitudes Data Sourcebook, 1947–1978

Philip E. Converse, Jean D. Dotson, Wendy J. Hoag, and William H. McGee, III

A unique record of trends in social and economic attitudes held by the American adult population over the past 30 years is available in book form from the Survey Research Center at the University of Michigan. Survey items include social class location, racial attitudes, views on women's roles, work and retirement, life quality, family financial situations, the state of the national economy, government spending and war and peace. 392 pp. $25.00

Injury to Insult

Unemployment, Class, and Political Response

Kay Lehman Schlozman and Sidney Verba

It is commonplace in contemporary American politics for those who experience economic strain to join together and ask the government for help, yet today's unemployed have not done so. Schlozman and Verba look closely at the unemployed and ask why not. The authors consider the political attitudes and behavior of the unemployed, as well as the changing role of social class in America and its implications. $20.00

Organization Without Authority

Dilemmas of Social Control in Free Schools

Ann Swidler

Here is one of the first systematic sociological treatments of the alternative organizations that emerged from the social and political movements of the 1960s and '70s. Based on rich, ethnographic case studies of two free schools, this book describes the distinctive patterns of leadership, social pressure, and social control that emerge in such organizations. $12.50

Harvard University Press

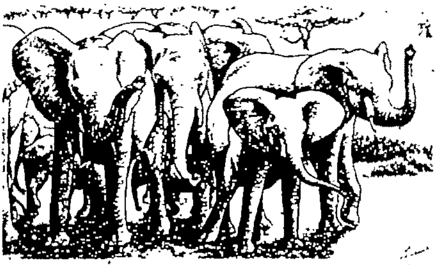
Cambridge, Mass. 02138

Sociobiology

The Abridged Edition

Edward O. Wilson

In this new edition, Wilson trims his monumental work to its essential argument. Eliminating technical discussions and data summaries, he retains the full basic structure of the original work. His controversial chapter on human social behavior is left intact.



Sarah Landry

"It is impossible to leave Wilson's book without having one's sense of life permanently and dramatically widened."
—Fred Hapgood, Atlantic

Belknap   96 illus. by Sarah Landry, 384 pp. $18.50 cloth; $9.95 paper

Themes of Work and Love in Adulthood

Neil J. Smelser and Erik H. Erikson, Editors

Leading experts in adult development explore the stages and crises adults pass through as they attempt to create meaningful lives for themselves. Contributors include: Neil J. Smelser, Erik H. Erikson, Ann Swidler, Robert LeVine, Daniel Levinson, Roger Gould, and Marjorie Fiske. The result is a book that has many unusual rewards. $15.00

Bastardy and Its Comparative History

Studies in the History of Illegitimacy and Marital Nonconformism

Peter Laslett, Karla Oosterveen, and Richard M. Smith, Editors

This is the first historical and sociological examination of bastardy in a variety of settings and over time. Illegitimacy during a four hundred year span in Britain, Western Europe, North America, and other countries is measured and placed in the larger perspectives of sexual conduct, social-cultural behavior, marriage, and economic change. This comprehensive volume will interest social historians, family historians, and all those engaged in writing sociological history. Studies in Social and Demographic History   480 pp. $35.00

Runnin' Down Some Lines

The Language and Culture of Black Teenagers

Edith A. Folb

With a Foreword by Claudia Mitchell-Kernan, Director,
Center for Afro-American Studies, UCLA

Folb spent eight years talking with black teenagers on the streets of south central Los Angeles, the ghetto area that includes Watts. Her skill in recording and interpreting the complex uses of the vernacular, "the lines," has led to this remarkable book on how these young people live—their actions, beliefs, attitudes, and values. More than a language, black teenage talk is a way to survive. Folb's book is an introduction to the dignity and ingenuity of that survival. $15.00

Harvard University Press

Cambridge, Mass. 02138

5 New Winners From Little, Brown

1. **SOCIAL PROBLEMS,** by Burton Wright and John P. Weiss. Cloth/556 pages/$15.95 tentative/with Instructor's Manual and Study Guide. This new introductory text features a unique integrating framework to help students examine 15 contemporary social problems. The authors consistently provide a useful historical background for each problem to show students how societal conflicts arise, are perpetuated, and, ultimately, might be solved.

2. **PRISONS IN TURMOIL,** by John Irwin. Paper/277 pages/$6.95 In his provocative new book, scholar and former prisoner John Irwin offers a fascinating account of how prisoners cope with prison life, including an analysis of the major types of social structures that arise in prisons.

3. **SOCIAL GERONTOLOGY: AN INTRODUCTION TO THE DYNAMICS OF AGING,** by David L. Decker. Cloth/c. 400 pages/$14.95 tentative/with Test Bank. This new text analyzes recent demographic shifts to explore the growing social significance of aging and discusses a wide variety of problems currently facing older Americans.

4. **THE SOCIOLOGY OF HEALTH: PRINCIPLES, PROFESSIONS, AND ISSUES,** by Fredric D. Wolinsky. Cloth/449 pages/$15.95 tentative. This comprehensive text focuses on major principles, professions, and issues of medical sociology and offers an in-depth analysis of the relationship between social factors and health.

5. **FAMILY IN TRANSITION: RETHINKING SEXUALITY, CHILD REARING, AND FAMILY ORGANIZATION,** Third Edition, edited by Arlene Skolnick and Jerome H. Skolnick. Paper/579 pages/$9.95 tentative/with Test Bank. In the Third Edition of this popular reader, **more than 70% of the material is new,** including a major new section on couples with articles on love, divorce, divorce law, and remarriage.

All of these new titles are **now available for examination.**

CHARLES C THOMAS • PUBLISHER

NEW CRIME AND THE ENVIRONMENT

By **K. D. Harries,** *Oklahoma State Univ., Stillwater.* This concise and pointed analysis focuses on the relationships of human and physical environments to the origin of criminal behavior.

Human environments are analyzed from two perspectives: *macroenvironmental* (national, regional, and urban) influences and *microenvironmental* (intraurban and local) influences. In the macroenvironmental context, the crime of homicide is used to illustrate the considerations which may enter interpretation of criminal behavior on the regional scale. Burglary, rape, assault, and robbery are then critically evaluated within the microenvironmental context. Recent studies also are examined for their strengths and weaknesses, and their essential findings are synthesized.

Later sections focus on the controversial and often misunderstood problems of population density and crowding, the relationship between crime and distance, and the role of environmental considerations in crime analysis and in criminal justice planning. Other topics discuss land use patterns, crime displacement, proximal space, and climate. *'80, 164 pp., 13 il., 21 tables, $14.00*

GAMBLING TODAY *edited by* **David Lester.** Gambling and gambling behavior are herein analyzed for their economic, sociological, criminological, legal, psychological, and psychiatric ramifications. *'79, $12.75*

POLICE OF AMERICA: A Personal View, Introduction and Commentary *by* **Harold K. Becker** *and* **Jack E. Whitehouse.** Topics include the need for police; their evolution, organization, training, and purpose; and reasons why their function is not to secure a crimeless society. *'79, $9.75*

SOCIAL CONFLICT AND MENTAL HEALTH SERVICES *by* **Robert D. Borgman.** Theory is interlaced with intervention strategies to provide a unique approach to such problems as suicide, homicide, school aversion, and adolescent social conflicts. *'79, cloth-$27.00, paper-$20.25*

CAREER DEVELOPMENT AND COUNSELING OF WOMEN *edited by* **L. Sunny Hansen** *and* **Rita S. Rapoza.** This text is concerned with the environmental and psychological variables which inhibit or facilitate all aspects of female development. *'78, $30.00*

SENTENCING: Process and Purpose *by* **Gerhard O. W. Mueller.** The American correctional system is examined, and alternatives to prison are presented. *'77, $18.50*

PUBLIC WELFARE SYSTEMS *by* **J. W. LaPatra.** Topics such as poverty, social policy, welfare, private and public attitudes, economics, politics, justice, and social services are considered. *'75, $16.00*

New! **THE KEEPERS: Prison Guards and Contemporary Corrections** *edited by* **Ben M. Crouch.** Chapters focus on selection and training of guards, styles of guarding, guard turnover, guard-inmate relations, and related subjects. *'80, $22.50*

PLURALISM IN EDUCATION: Conflict, Clarity, and Commitment *by* **Richard Pratte.** This text exposes the negative influence of ideologies that mask outmoded educational policies and practices. *'79, cloth-$15.75, paper-$9.75*

OUR CHILDREN SHOULD BE WORKING *by* **William N. Stephens.** The role of work in shaping the character, individual work habits, and personal initiative of children is analyzed in this text. *'79, $12.75*

PROGRESS IN BEHAVIOR THERAPY WITH DELINQUENTS *compiled and edited by* **Jerome S. Stumphauzer.** Numerous treatment, training, and preventive programs in both institutional and community settings are examined. *'79, cloth-$32.75, paper-$25.00*

CREATING COMMUNITY ACCEPTANCE FOR HANDICAPPED PEOPLE *by* **Roberta Nelson.** The author discusses physical and attitudinal barriers, ways to elicit support from the community, and issues of habilitation and rehabilitation. *'78, $16.25*

CIVIL LITIGATION AND THE POLICE: A Method of Communication *by* **Robert H. Sulnick.** The author shows how civil litigation can be used as a form of communication to elicit institutional policy changes. *'76, $13.75*

Conflict and Conflict Management

JOSEPH S. HIMES

In a book that will have wide classroom use, Mr. Himes provides an overview of social conflict and its management. Drawing from social science literature, theory, and research, he effectively demonstrates that contemporary social science can provide answers to the most often asked questions about conflict, its causes, its consequences, its prevention, and its prediction. $23.00 *cloth*, $9.00 *paper*

The Concept of Ideology

JORGE LARRAIN

Foreword by Tom Bottomore

The problem of ideology is at the center of many disciplines and interests within the social sciences. Mr. Larrain deals in a comprehensive and original way with the concept and makes important critical comments on a number of problems that are at the center of recent discussions of social theory, especially Marxist theory—among them ideology and science, ideology and linguistic analysis, and the controversy between historicism and structuralism. $18.00

Ethnic Soldiers

State Security in Divided Societies

CYNTHIA H. ENLOE

Professor Enloe investigates an unusual and highly important theme: the relationship between military organization and racial or ethnic identities. Her ethnic perspective on this subject represents a completely new approach to the problem of internal state security and the mobilization of armed forces. Yet the reader of *Ethnic Soldiers* will quickly realize how crucial this relationship is and wonder that it has been so long neglected. The recent renaissance of ethnic sentiments and loyalties coupled with the serious attention being given by scholars to ethnic politics makes this book of immediate concern to a wide spectrum of anthropologists, sociologists, political scientists, philosophers, and historians. $19.00

SOCIAL ORIGINS OF THE IRISH LAND WAR

Samuel Clark

From 1879-1882, thousands of Irish agricultural tenants revolted against their landlords and set in motion the two decades of political struggle that eventually resulted in the demise of Irish landlordism. This thorough and convincing study examines the most formidable challenge to established authority that emerged in Ireland between the Rebellion of 1798 and the Revolution of 1916-1921. Cloth, $25.00. Limited Paperback Edition, $8.95

AFRICAN BUSINESSMEN AND DEVELOPMENT IN ZAMBIA

Andrew A. Beveridge and Anthony R. Oberschall

Many new African states have sought to reduce foreign control of their economies and have created unprecedented business opportunities for black Africans; yet these new entrepreneurs have received little scholarly attention. Beveridge and Oberschall examine the rapid growth of the indigenous African business sector in Zambia, and systematically link this growth to the country's social structure and its "dependent" economic status. $22.50

THE CENTRALIST TRADITION OF LATIN AMERICA

Claudio Véliz

Surveying some five hundred years of history, this intelligent study shows why the European tradition of development cannot apply to the efforts to reform, modernize, or revolutionize Latin America, and offers a coherent appreciation of the centralist tradition that has shaped Latin American society. Cloth, $22.50. Limited Paperback Edition, $9.75

RELUCTANT FEMINISTS IN GERMAN SOCIAL DEMOCRACY, 1885-1917

Jean H. Quataert

Examining the convergence of socialism and feminism in the German labor movement around the turn of the century, Jean Quataert probes the competing identities and loyalties of class and sex and the problems their adherents faced in reconciling the two. By focusing on the women's movement in particular, she expands our understanding of the German Social Democratic subculture and shows that socialist feminism was far more important than previously recognized. Illus. $18.50

PALESTINIAN SOCIETY AND POLITICS
Joel S. Migdal
Relying principally on archival sources and interviews, and using a variety of methodologies and analytic perspectives, the contributors to this volume focus on the changing nature of the Arab population in Palestine and the leadership to which that population looks. *Written under the auspices of the Center for International Affairs, Harvard University*
Cloth, $20.00 Paper, $6.95

SOMEONE, NO ONE
AN ESSAY ON INDIVIDUALITY
Kenelm Burridge
As categories of moral action, the individual and individuality lie at the center of Western civilization. Kenelm Burridge asks if this reflects the development of a universal in human experience, or if in some sense it is tied to a specific cultural tradition. Through the use of ethnographic information in what previously has been an exclusively philosophical discussion, he seeks the roots of Western individuality in cross-cultural and historical contexts. Whereas most studies of individuality begin with psychodynamics, this one examines the ways in which social processes become internalized and imbedded within the self.

Community Power and Political Theory
A Further Look at Problems of Evidence and Inference
Second, enlarged edition
Nelson W. Polsby
Since 1963, when the first edition of this book was published, the field of community power studies has flourished in a variety of ways. In this new edition, Nelson Polsby addresses some of the central issues in philosophy of social science, theory, and methodology engaged by this literature over the last fifteen years.

"**A classic study has been made even greater.** I know of no other single work that embodies the theoretical, the empirical and the methodological in as creative a fashion in the social sciences as does this second edition of *Community Power and Political Theory*. It is Polsby at his best."

INTERNATIONAL POPULATION CENSUS BIBLIOGRAPHY

Revision and Update, 1945-1977

(Texas Bibliography II)

Compiled by DOREEN S. GOYER

A Volume in the STUDIES IN POPULATION Series

The original *International Population Census Bibliography* (six volumes and one supplement) contained over 14,000 citations of publications from the first census to those taken in the mid 1960's of about 200 countries and territories. The *Revision and Update* has over 13,000 citations of reports from population censuses taken from 1945 through 1977, almost as many publications in the last thirty-two years as there were in the over 200-year period preceding. No other reference work in the field duplicates exactly the scope of these publications. The *Revision and Update* is not just a bibliography that extends the coverage of the original IPCB to the present; it is a reference tool to aid the researcher and guide the librarian through the maze of census publications. For the researcher it presents the results of a country's census production in a logical manner using familiar bibliographic descriptions. It tells where a copy of almost every item listed may be found in the United States for consultation in person or via interlibrary loan. On the surface it may seem to have many more conveniences for the librarian; but if the librarian has control of the literature, the researcher reaps the benefits.

The Table of Contents contains a list of the 211 countries and territories covered in the volume.

1980, 592 pp., $39.50 ISBN: 0-12-294380-5

SOCIOLOGICAL DILEMMAS

Toward a Dialectic Paradigm

By PIOTR SZTOMPKA

ESSAYS IN MEDICAL SOCIOLOGY
Journeys Into the Field

Renee C. Fox, University of Pennsylvania

This outstanding collection of essays explores the complex interrelationships between medicine, science, religion, and magic, set in a variety of medical settings in the United States, Belgium, and Zaire.

(1-27040-7)/1979/548pp./$19.95

DEATH AND EXISTENCE
A Conceptual History of Human Mortality

James P. Carse, New York University

A systematic survey of ten distinct conceptions of death as they are found in the world's major religious and philosophic traditions, illuminating the questions of contemporary persons about the nature of their own mortality. (1-13704-9)

February 1980/approx. 480pp./ $22.50 (tent.)

WELFARE OF THE ELDERLY An Economic Analysis and Policy Prescription

W. Kip Viscusi, Northwestern University

A systematic analysis of the economic needs of the aged, the motivations for government intervention, the government policies that affect the well-being of the aged, and policy reforms that can promote the welfare of the elderly.

(1-01506-7)/1979/251pp./$18.95

TRUST AND POWER

Miklas Luhmann, University of Bielefeld, German Federal Republic

One of Germany's leading social theorists offers a novel, theoretical treatment of these two social relationships, examining their wide-ranging significance in social, political, and economic life.

(1-99758-7)/1980/228pp./$28.95

Rare & Broad Insights & Perspectives.

THEORIES OF ORGANIZATIONS
Form, Process, and Transformation

Jerald Hage, University of Maryland

A systematic statement about organizations, including how the organizational form maintains itself, how it changes, and what factors are involved. The text approaches the problem from the perspectives of power, change, human factors, resources, and the environment. (1-33859-1)

April 1980/approx. 435pp./ $19.95 (tent.)

Man in the Age of Technology

ARNOLD GEHLEN, TRANSLATED BY PATRICIA LIPSCOMB. With a Foreword by Peter L. Berger. Probing the crisis of human personality in our century, *Man in the Age of Technology* traces the dizzying social after-effects resulting from the loss of the institutions that grew out of and sustained an earlier, agrarian age. First published in Germany in 1949 and translated here for the first time, this seminal work by Arnold Gehlen reflects his lifelong concern with the need of man to stabilize his life by constructing his own world. $15.00

Programmed to Learn

An Essay on the Evolution of Culture

H. RONALD PULLIAM AND CHRISTOPHER DUNFORD. This spirited analysis of the evolution of behavior provides a stimulating new view of the central role of learning in the origin and maintenance of cultures. Offering an alternative approach to the currently controversial topics in sociobiology, the authors argue that cultural evolution owes its origins and rules to genetic evolution, but has a momentum all its own. "Timely, accessible, and very readable."—*Library Journal* $10.00

Announcing:

The Age of Structuralism

Lévi-Strauss to Foucault

EDITH KURZWEIL. This lucid study of the sociological, political, and philosophical currents of structuralism offers introductions to eight prominent French thinkers—five who fueled the movement and three who provided intellectual opposition. Examining the work of Claude Lévi-Strauss, Louis Althusser, Roland Barthes, Jacques Lacan, Michel Foucault, Henri Lefèbvre, Alain Touraine, and Paul Ricoeur, *The Age of Structuralism* provides a lively and clear portrait of a movement whose impact still reverberates today. $20.00 cloth, $6.95 paper

First Encounters with Eminent Social Thinkers

THE PLEASURES OF SOCIOLOGY is a refreshing, original introduction to sociology under the editorship of Lewis A. Coser, noted author and teacher.

Its 36 remarkable essays include:

- Social "truths" that are really lies
- The dynamics of crime in America
- Labor and alienation
- The conspicuous consumption of the moneyed class
- The sexual code of the slums
- The social roles of the stranger and the fool
- The pioneering lifestyle of modern urban "night people"
- and much, much more

QUALITATIVE SOCIOLOGY

Editors: Barry Glassner, Ph.D. and
Derral Cheatwood, Ph.D.

This journal has been recognized throughout the social sciences as a leading source devoted to the qualitative interpretation of social life. A broad spectrum of topics and research methods are featured including theoretical essays, fieldwork studies, discussions of the philosophy of social science, photographic studies, and qualitative interpretations of quantitative data. Specific subjects which have been examined include the theories of Weber, Parsons, Marx, and other prominent social scientists.

GUIDED CHANGE OF THE AMERICAN HEALTH SYSTEM

Where the Levers Are

This book provides an in-depth analysis of the processes and mechanisms of deliberate and constructive social change. Specifically, four proposals for reforming some aspect of the American health system — each developed by a special study group, commission or task force — are examined. Implicit in each of the proposals is an alternative theoretical perspective for effecting social change. Each plan, therefore, focuses on a different set of variables to provide the "levers" for change.

PARAPROFESSIONALS IN THE HUMAN SERVICES

Volume VI, Community Psychology Series

This work provides a critical assessment of the effectiveness of paraprofessionals in the human services, and examines the unique problems and potentials of this burgeoning work force. It begins with an historical analysis, and then explores economic, training and recruitment considerations. Various essays document the extent of paraprofessional employment, the nature of the services rendered, and the quality of the paraprofessionals' performance. The authors discuss problems in the establishment of training programs, and difficulties and strategies for research and evaluation of paraprofessional programs.

COLLABORATION IN ORGANIZATIONS

Alternatives to Hierarchy

Most organizations and social systems in Western society utilize hierarchical structures which promote competition as a major value system and an individual behavior pattern. This challenging book introduces the concept and application of collaboration as an alternative value system and organizational structure. The collaborative model reinforces individual development and contribution, and provides a viable framework for organizing a social system.

THE ADMINISTRATION OF JUSTICE

Law Enforcement, Courts, and Corrections

This comprehensive text provides students with an overview of the organization and operations of the three major criminal justice agencies: law enforcement, courts, and correctional facilities. The authors examine the relationships among the agencies, and describe the general procedures of each agency at the local, state and federal levels. For those who are considering criminal justice careers, the text explains the roles and responsibilities of professionals within each of the agencies.

Machine Politics in Transition
Party and Community in Chicago
Thomas M. Guterbock

For three years, Thomas M. Guterbock participated in the daily activities of the Regular Democratic Organization in one North Side Chicago ward in order to discover how political machines win the support of the urban electorate.

Cloth 352 pages $20.00 March

La Chicana
The Mexican-American Woman
Alfredo Mirandé and
Evangelina Enríquez

Very little is known about the contributions or the history of Chicanas. They experience multiple forms of oppression as women, as members of a colonized group, and as members of a culture perceived to be dominated by males. *La Chicana* offers a definitive study of this long neglected group.

Cloth 281 pages Illus. $19.50. Available

Alexis de Tocqueville
On Democracy, Revolution and Society
Edited by John Stone and
Stephen Mennell

This collection is the first to include excerpts from Tocqueville's two acknowledged masterpieces, *Democracy in America* and *The Ancien Régime and the French Revolution*, as well as excerpts from his extensive correspondence, notebooks, the *Recollections*, and the government reports and newspaper articles that he wrote while a member of France's Chamber of Deputies.

Before the Convention
A Theory of Presidential Nomination Campaigns
John A. Aldrich

Political scientist John Aldrich presents a systematic analysis of presidential nomination politics, based on application of rational-choice models to candidate behavior. He seeks to determine why and how candidates choose to run,, why some succeed and others fail, and to determine what consequences the nomination process has for the general election and, later, for the president in office.

Notice to Contributors

A processing fee of $10 is required for each paper submitted, except for comments; such fees will be waived for student members of ASA. A check or money order, made payable to the American Sociological Association, should accompany each submission. The fee must be paid in order for the review process to begin.

The length of an *ASR* paper is generally ten (10) printed pages or thirty (30) typed pages. However, the *ASR* is happy to accept manuscripts up to fifty (50) typed pages in length for review. We also are interested in receiving manuscripts for a Research and Notes Section.

To permit anonymity in the review of manuscripts, keep identifying material out of the manuscript. Attach a cover page giving authorship, institutional affiliation and acknowledgments, and provide only the title as identification on the manuscript and abstract.

ASA Multiple Submissions Policy: Submission of a manuscript to a professional journal clearly implies commitment to publish in that journal. The competition for journal space requires a great deal of time and effort on the part of editorial readers whose only compensation for this service is the opportunity to read papers prior to publication and the gratification associated with discharge of professional obligation. For these reasons, *the American Sociological Association regards submission of a manuscript to a professional journal while that paper is under review by another journal as unacceptable.*

SUBMISSION AND PREPARATION OF MANUSCRIPTS

1. Submit four (4) copies and retain the original for your files. Copies may be Xerox, mimeograph or multilith, but not carbons.
2. Enclose a stamped self-addressed postcard for acknowledgment of manuscript receipt. *Manuscripts will not be returned.* Please do not send your original copy.
3. All copy must be typed, doublespaced (including indented material, footnotes and references) on 8½ by 11 inch white opaque paper. Lines must not exceed six (6) inches. Margins must be a minimum of one inch.
4. Include four (4) copies of an abstract of no more than 150 words.
5. Type each table on a separate page. Insert a location note at the appropriate place in the text; e.g., "Table 2 about here." Send copies, retain originals.
6. Figures must be drawn in India ink on white paper. Send copies, retain originals.
7. Clarify all symbols with notes in the margins of the manuscript. Circle these and all other explanatory notes not intended for printing.
8. Footnotes should not be placed in the body of the text. Type them (doublespaced) and attach them as a separate appendix to the text. Number them consecutively throughout the text. Footnotes are to be kept to a minimum and used only for substantive observations. Source citations are made within the text rather than in footnotes.
9. Acknowledgments, credits and grant numbers are placed on the title page with an asterisk.

REFERENCE FORMAT

A. *In the text:* All source references are to be identified at the appropriate point in the text by the last name of the author, year of publication and pagination where needed. Identify subsequent citations of the same source in the same way as the first, not using *"ibid.," "op. cit.," or "loc. cit."* Examples follow:

1. If author's name is in the text, follow it with year in parentheses. [". . . Duncan (1959) . . ."]
2. If author's name is not in the text, insert, in parentheses, the last name and year, separated by a comma. [". . . (cf. Gouldner, 1963) . . ."]
3. Pagination (without "p." or "pp.") follows year of publication after a colon. [". . . Kuhn (1970:71)."]
4. Give both last names for dual authors; for more than two use "et al." in the text. When two authors have the same last name, use identifying initials in the text. For institutional authorship, supply minimum identification from the beginning of the complete citation. [". . . (U.S. Bureau of the Census, 1963:117) . . ."]
5. Separate a series of references with semicolons and enclose them within a single pair of parentheses. [". . . (Burgess, 1968; Marwell et al., 1971; Cohen, 1962) . . ."]

B. *In the appendix:* List all source citations by author, and within author by year of publication, in an appendix titled "References." The reference appendix must be complete and include all references in the text. The use of "et al." is not acceptable in the appendix; list the names of all authors. (See A. 4. for text format.)

If there is more than one reference to the same author and year, distinguish them by the letters, a, b, etc. added to the year. [". . . Levy (1965a:331) . . ."] Give the publisher's name in as brief a form as is fully intelligible. For example, John A. Wiley and Sons should be "Wiley." If the cited material is unpublished, use "forthcoming" with name of journal or publisher; otherwise use "unpublished."

Use no underlining, italics or abbreviations.

Examples follow:

1. *Books:* Jud, Gerald J., Edgar W. Mills, Jr. and Genevieve Walters Burch
   1970 Ex-Pastors. Philadelphia: Pilgrim Press.
   U.S. Bureau of the Census
   1960 Characteristics of Population. Volume 1. Washington, D.C.: U.S. Government Printing Office.
   Bernard, Claude
   [1865] 1957 An Introduction to the Study of Experimental Medicine. Tr. Henry Copley Greene, New York: Dover.
2. *Periodicals:* Conger, Rand
   Forthcoming "The effects of positive feedback on direction and amount of verbalization in a social setting." Pacific Sociological Review.
   Merton, Robert K.
   1963a "The ambivalence of scientists." Bulletin of The Johns Hopkins Hospital 112:77–97.
   1963b "Resistance to the systematic study of multiple discoveries in science." European Journal of Sociology 4:237–82.
3. *Collections:* Davie, M.
   1938 "The pattern of urban growth." Pp. 133–61 in G. Murdock (ed.), Studies in the Science of Society. New Haven: Yale University Press.

See recent issues for further examples.

SCOPE AND MISSION OF AMERICAN SOCIOLOGICAL REVIEW: The *American Sociological Review* publishes work of interest to the discipline in general, new theoretical developments, results of research that advance our understanding of the most fundamental social processes, and important methodological innovations. Like other publications of the Association, emphasis is given to exceptional quality. Unlike the more specialized journals of the Association, the *American Sociological Review's* primary focus is on whatever has the most general bearing on the knowledge of society.

Concerning manuscripts, address: Editor, *American Sociological Review*, Department of Sociology, University of Illinois, Urbana, Illinois 61801. (217) 333-6515.

The *American Sociological Review* (ISSN 0003–1224) is published at 49 Sheridan Avenue Albany, New York, bimonthly in February, April, June, August, October, and December.

Applications for permission to quote from this journal should be addressed to the Executive Office

Copyright © 1980 American Sociological Association.

Annual membership dues of the American Sociological Association, $20–$120 ($10 of this amount may cover a subscription to the *American Sociological Review*); Associate, $25; International Associate, $25; Student Associate, $12.

Application for membership and payment of dues should be made to the Executive Office. Subscription rate for members, $10; nonmembers, $15; institutions and libraries, $30; nonmember students, $10. Single issue, $4.

New subscriptions and renewals will be entered on a calendar year basis only.

Change of address: Six weeks advance notice to the Executive Office and old address as well as new are necessary for change of subscriber's address.

Concerning advertising, changes of address, and subscriptions, address: Executive Office, American Sociological Association, 1722 N Street, N.W., Washington, D.C. 20036.

Claims for undelivered copies must be made within the month following the regular month of publication. The publishers will supply the missing copies when losses have been sustained in transit and when the reserve stock will permit.

Second class postage paid at Washington, D.C. and additional mailing offices.

AMERICAN SOCIOLOGICAL REVIEW

SOLIDARITY MODEL, BREAKDOWN MODEL, AND THE BOSTON ANTI-BUSING MOVEMENT*

BERT USEEM
Center for Research on Social Organization
University of Michigan

American Sociological Review 1980, Vol. 45 (June:357–369)

"Breakdown theorists" assert that actors who are weakly integrated into their community and experience discontent are likely to join a protest movement. These analysts also maintain that disorganization increases discontent. "Solidarity theorists," on the other hand, argue that isolated individuals are less likely to protest than others and that discontent is unrelated to protest. Data from a survey of Boston residents provide support for the solidarity theorists' argument that social cohesion increases protest. The Boston data, however, support the breakdown theorists' hypothesis that discontented individuals are more likely to protest than others. Finally, the data undercut the breakdown theorists' hypothesis that disorganization increases discontent.

Social movement analysts sharply disagree over the reasons for popular participation in social movements. Some researchers advocate a "solidarity" model while others favor a "breakdown" model. The central hypothesis of the solidarity model is that social solidarity, the integration of individuals into community life, facilitates the mobilization process for two reasons. First, social solidarity furnishes individuals with a communication network, a set of common values and symbols around which members can be mobilized, a tradition of participation in group activity, and an authority structure. On the basis of empirical research, solidarity theorists maintain that, unless the particular conditions associated with social solidarity are present, mobilization is unlikely to take place (Shorter and Tilly, 1974; Tilly, 1978).

Second, solidarity makes "bloc mobilization" possible. Movements can expand either by recruiting individuals one by one or by enlisting entire blocs of previously organized people en masse. Mobilization is made much easier when ongoing movements are able to draw previously established groups into their organization. By definition, bloc mobilization is impossible unless some measure of solidarity exists within a community (Oberschall, 1973:125).

Anthony Oberschall (1978:297–8) summarizes the breakdown model:

> (B)reakdown theory points to the dissolution of traditional social formations and communal solidarities as a result of rapid social change. Social disorganization, demographic pressures, and ecological imbalance lead to the accumulation of strains, frustrations, insecurity, and grievances, and the resulting pressure cooker has a tendency to explode in collective violence and civil disorder.

The breakdown model has two variations (see Figure 1). According to the "mass society" version, individuals are most likely to join social movements when they have few personal ties within a community and a weak sense of identification with that community. Social isolation facilitates recruitment by detaching individuals from the structures that normally channel people into conventional political

I would like to thank Ellen Messing, Mayer Zald, Robert Leibman, Charles Tilly, and Ronald Kessler for their helpful comments on this paper. This research was supported by grants from the National Science Foundation (No. Soc-6800621) and the Society for the Psychological Study of Social Issues.

1. Breakdown Model
   - A. Mass Society Version (e.g., Kornhauser, Coleman)
     Social Disorganization——→Protest
   - B. Discontent Version (e.g., Piven and Cloward, Gurr)
     Social Disorganization→Discontent→Protest
2. Solidarity Model (e.g., Tilly, Oberschall)
   Solidarity——→Protest

Figure 1. Two Versions of Breakdown Model and Solidarity Model on the Relationship among Social Disorganization/Solidarity, Discontent, and Protest.

activity (Coleman, 1957; 1971; Kornhauser, 1959). Mass society theorists assert that secondary organizations, such as fraternal groups and political clubs, are especially important in preventing people from participating in social movements. Thus, in contrast to the solidarity model, proponents of the mass society model argue that socially isolated individuals are more, not less, likely to become involved in social movements.

A second version of the breakdown argument, called the "discontent model," stresses the significance of changes in a population's level of discontent for explaining participation in social movements (Gurr, 1970; Piven and Cloward, 1977). According to this argument, individuals strongly integrated into their community are normally insufficiently discontented to participate in social movements. Individuals with weak bonds to their community, on the other hand, usually experience heightened levels of discontent. The more discontented an individual, the more likely is he or she to participate in a social movement. Thus, the hypothesized process has two steps: social disorganization increases discontent which, in turn, motivates protest. It should be noted that researchers have been particularly interested in the effects of one form of discontent, "relative deprivation." Relative deprivation refers to the feeling that one is deprived of a desired object, in comparison to other persons not being deprived of it.

Solidarity theorists, by contrast, have generally denied the usefulness of focusing on any form of discontent. They maintain that grievances are sufficiently widespread through all societies at all times that, as a constant,[1] they explain little of the variation in social movement participation (Jenkins and Perrow, 1977:266; Oberschall, 1978:298).[2]

Studies have tested both models. One major effort has been the research associated with Charles Tilly (Lodhi and Tilly, 1973; Rule and Tilly, 1972; Shorter and Tilly, 1974; Snyder and Tilly, 1972; Tilly et al., 1975). The Tilly group has focused on testing a solidarity model explanation of why the large-scale transformations that accompanied industrialization changed the preexisting pattern of collective behavior in several European countries. The research group's central conclusion is that industrialization created a proliferation of new organizations capable of contending for power. The establishment of cities, for example, promoted the growth of community organizations, some of which sought new political rights as they matured. Similarly, factory life created a new form of organization, the union, which frequently took political action.

Other work favorable to the solidarity model has shown that group membership may facilitate protest. These studies have revealed a positive association between membership in secondary and primary groups and participation in the Social Credit party in Quebec, Canada (Pinard, 1971); a civil rights sit-in protest in the early 1960s (Von Eschen et al., 1971); the feminist movement in the late 1960s (Freeman, 1973; 1979); and the Pentecostal (Gerlach and Hine, 1970; Heirich, 1977) and Nichiren Shoshu (Snow, n.d.) religious movements.

Other research, for example that of Piven and Cloward (1977), supports the breakdown model. Piven and Cloward examined four poor people's movements that emerged in the United States during the 1930s and the 1960s. They found that prior to each movement's start, a profound social change had destroyed the "regulatory controls inherent in the structure of institutional life" (p. 10). The destruction of these regulatory mechanisms increased discontent which, in turn, led to mass defiance. The Great Depression, for example, dislodged large numbers of people from the regulatory controls inherent in the work situation. As a result, frustration increased, which led to a movement of the unemployed who engaged in spontaneous street demonstrations, rent and food riots, and disruptions of relief centers (pp. 41–92).

---

[1] It should be noted that Jenkins and Perrow argue that one should assume that discontent is constant "especially" when analyzing "deprived groups" (1977:266). They do not discuss whether this assumption is appropriate when studying nondeprived groups, nor do they provide criteria for distinguishing the two.

[2] One solidarity theorist, Tilly (1978:56–72), has recently reformulated his model so as to include a discontent factor (cf. Tilly, 1975). Still, even in the reformulated version, it is assumed that discontent factors are secondary to social organizational factors in accounting for the variance in the level of collective action.

Also consistent with the breakdown model are several studies of the relationship between discontent and participation in the United States urban revolts of the 1960s. Research on riot participation—in three different cities—by Crawford and Naditch (1970), Caplan and Paige (1968), and Bowen et al. (1968) all showed a positive correlation between relative deprivation and involvement in the rebellions. In contrast, however, McPhail (1971:1064) reanalyzed the data from numerous riot studies and concluded that the discontent explanation "receives scant empirical support."[3]

While there are numerous studies testing either the breakdown model or the solidarity model,[4] few have compared the two models using the same data. One exception is the research conducted by the Tilly group mentioned above. Since their research is based on archival material, however, they are forced to rely on highly indirect measures of several key variables. In one study, for example, Snyder and Tilly (1972) measure relative deprivation based on indices of food prices, prices of manufactured goods, and industrial production. Their central finding is that relative deprivation is unable to explain the year-to-year fluctuation between 1830 and 1960 in the number of collective behavior participants in France. It is unclear, however, whether the several indices of objective conditions did, in fact, tap subjectively perceived deprivation.

Thus, although a central debate in social movement theory is between proponents of the solidarity model and advocates of the breakdown model, the available studies have not clearly established which model is best able to account for protest. Research is unsatisfactory because, first, studies have infrequently compared the explanatory power of the two models with respect to the same data. Second, the few exceptions have relied on highly indirect measures of critical variables.

The purpose of this article is to compare the value of the breakdown and solidarity models in explaining support of and participation in the Boston anti-busing movement. We will address the following questions about popular participation in the anti-busing movement. First, did social solidarity promote or inhibit participation in the anti-busing movement, as would be respectively argued by solidarity and mass society theorists? Second, did discontent contribute to involvement in the anti-busing movement, as theorists using the discontent version of the breakdown model would argue? Or is there no relationship between discontent and participation in the anti-busing movement, as the solidarity theorists would maintain? Finally, did social disorganization increase discontent, as the breakdown theorists would predict?

---

[3] Research using aggregate data on the characteristics of riot cities has also produced contradictory results. Spilerman (1970; 1971; 1976) found that measures of black deprivation cannot account for the riots. In contrast, Morgan and Clark (1973) show that grievance levels are strong predictors of the riots.

[4] Additional studies that support the breakdown model include Smelser's (1962) analysis of collective behavior; Huntington's (1968) analysis of political order and revolution in modernizing societies; Gurr's (1970) and Davies's (1962) application of relative deprivation theory to civil strife and revolution; and explanations by Katznelson (1978) and Miller et al. (1976) of the United States urban riots during the 1960s.

Studies that support the solidarity model include Jenkins and Perrow's (1977) study of the unionization of California farmworkers; Wolf's (1969) and Useem's (1977) analyses of peasant participation in revolutionary movements; and Oberschall's (1973:204–41) explanation of the emergence of the Civil Rights movement in the South.

1. Data

The term "Boston anti-busing movement" is here used to refer to the collective, widespread, but not necessarily organized, effort that had the stated goal of preventing busing for the purpose of school desegregation and which used noninstitutionalized means to achieve its goals. The movement emerged in the fall of 1974 and, over the next four years, it mobilized people to join school boycotts; to support neighborhood "information centers"; to form a city-wide organization, Restore Our Alienated Rights (ROAR); and to participate in dozens of mass demonstrations, some of them violent.

Data for the analysis are drawn from a survey of 468 white Boston residents between the ages of 25 and 53 who were United States citizens.[5] To simplify the analysis and to insure that an adequate number of anti-busing activists were in the sample, interviewing was restricted to neighborhoods that were predominantly white, that were heavily affected by the federal court's busing order, and that were locations of anti-busing activities.[6] The sample was drawn from the 1977 City of Boston "Annual Listing of Residents," which provides names, addresses, birthdates, and citizenship information. Respondents were selected in "clusters" of three.

Eleven trained professional interviewers, and the author, conducted the interviews between December, 1977, and April, 1978. Although the interviewing period extended over several months, no important events relating to the busing controversy occurred during this period. Thus, it is unlikely that the delay between the first and last interviews introduced bias into the data. Interviewers were instructed to interview only those respondents who were selected in the sample and to make at least three attempts to interview each potential respondent. Sixty-five percent of the people selected were interviewed.

2. Dependent Variables

This study uses two dependent variables. "Attitudinal support for the anti-busing movement" (SUPPORT) measures the extent to which respondents identified with the anti-busing movement and endorsed its goals and tactics. The scale was derived from two questions. First, respondents were asked how strongly they supported or opposed the following items: school boycotts to protest forced busing, the establishment of private academies for students who refused to be bused, attending anti-busing protest marches, and participation in anti-busing groups. Second, respondents were asked how much "in common" they felt with anti-busing demonstrators and the anti-busing group ROAR. Cronbach's alpha for the SUPPORT scale was .866, which suggests the scale is reliable.[7]

The "PARTICIPATE" scale measures participation in anti-busing activities and groups. The scale is derived from the responses to two sets of questions. First, respondents were asked if they participated in school boycotts, the establishment of private academies, protest marches, or organized anti-busing groups. Second, respondents were asked separately if they had been active in any of nine specific anti-busing organizations. Respondents were scored a "point" each time they mentioned having participated

---

[5] Residents over 53 years old and under 25 were excluded for two reasons. First, evidence from pretest interviewing and attendance at anti-busing rallies and meetings indicated that a very high proportion of the people involved in the anti-busing movement were parents of school age children. Excluding the over-53 and under-25 age groups, therefore, increased the proportion of anti-busers in the sample.

Second, a relatively high percentage of Boston residents are elderly (Tilly, 1965:6). Research in other contexts (e.g., Marsh, 1977) indicates that elderly people infrequently join social movements. In addition, in pretest interviewing it was found that the majority of Boston's elderly are so often overwhelmed by their own personal problems that they are unlikely to join any movement. Thus, since elderly residents were not likely to participate in the anti-busing movement for reasons not relevant to our research interests, they were excluded from the sample.

[6] The three neighborhoods meeting these criteria are South Boston, Hyde Park, and West Roxbury.

[7] See Useem (1979:chap. 2) for a full discussion of the reliability and validity of the dependent variables.

Table 1. Rotated Factor Matrix for Solidarity Items

Variable		Factor 1	Factor 2	Factor 3
a.	Feels a great deal in common with people in neighborhood	.092	.122	.655
b.	Feels strong ties to neighborhood	.098	.139	.700
c.	Long residence in neighborhood	.069	.003	.502
d.	Long residence in Boston	.080	−.028	.585
e.	Owns home	.132	.215	.143
f.	Belongs to secondary organizations	.216	.599	−.082
g.	Attended meeting, dinner, or rally for candidate in recent local election	.084	.706	.195
h.	Worked for candidate in recent local election	−.043	.749	.213
i.	Wore a campaign button or put a campaign sticker on car in recent local election	−.022	.615	.292
j.	Voted in recent local election	.262	.283	.202
k.	Wrote public official giving opinion about something that should be done	.230	.473	−.251
l.	Wrote a letter to the editor of a newspaper giving political opinion	.145	.589	−.286
m.	Talked about politics and public affairs with family and relatives	.751	.024	.033
n.	Talked about politics and public affairs with people at work	.750	.160	.092
o.	Talked about politics and public affairs with friends and neighbors	.829	.110	.102
p.	Talked about politics and public affairs with community leaders, people in politics	.327	.579	.001
	Percentage of total variance:	23.4%	11.1%	9.2%
Percentage of variance accounted for by all 3 factors:	43.7%			

□Indicates a loading above .400.

in an anti-busing activity or organization.[8] A Cronbach's alpha of .828 for the PARTICIPATE scale indicates that it is reliable.

3. *Solidarity Model versus Mass Society Model*

As the first step in assessing the relationship between the dependent variables and social solidarity, indices of social solidarity were developed. "Social solidarity" is defined as the extent to which people participate in organized groups and are objectively and subjectively attached to their community. Two measures of solidarity are, therefore, used. One, labelled "group participation," measures a respondent's participation in various group activities. A second index of solidarity, "community attachment," measures a respondent's bonds with his or her community.

Our questionnaire included sixteen measures of solidarity. To substantiate the hypothesis that the two dimensions of solidarity have distinct empirical referents, the measures of solidarity were factor analyzed. The results of the factor analysis are reported in Table 1.[9] Factor loadings above .400 are circumscribed. The factor extracted in the third column confirms our expectation of the existence of a community attachment dimension. Forming this dimension are questions on feelings of being similar to or different from one's neighbors, feelings of ties to one's neighborhood, and length of residence in Boston and in one's neighborhood.

The factor loading in the first and second columns reveals that group participation has two nearly independent components, rather than the single dimension as originally hypothesized. The factor extracted in the second column appears to represent activity within secondary groups. The items loading highly on this factor are a scale measuring active membership in any of fourteen voluntary organizations (e.g., fraternal lodge, veterans' organization, labor union); a series of questions on nonvoting forms of involvement in a local campaign; a question on writing public officials and newspapers or magazines; and questions on talking with community leaders and people in politics.

---

[8] We created a three-category scale of participation in the anti-busing movement. Respondents were categorized as scoring either 0 (no participation in any of the activities or groups), 1 (participation in one and only one anti-busing activity or group), or 2 (participation in two or more such activities). We truncated the scale since we cannot meaningfully discriminate, for example, between respondents who participated in two activities from respondents who participated in three or four activities. The validity of the recoding strategy is supported by the fact that the correlates of the recoded PARTICIPATE scale are higher than when the full range of values is used.

[9] The solution was computed using a principal component factor procedure and a varimax rotation.

The factor extracted in the first column appears to represent activity within primary groups. The items include the questions on talking about politics and public affairs with family and relatives, with people at work, and with friends and neighbors.

Using the factor scores derived from the factor analysis, we can construct three scales labelled "community attachment," "secondary group participation," and "primary group participation." It should be noted, however, that the questions making up the primary group participation scale are very limited in number and range. The scale has only three questions and they all ask the respondents about "talking about politics." Thus, findings based on the use of this scale should be interpreted with particular caution.

Having constructed measures of solidarity, we now compare the usefulness of the solidarity and mass society version of breakdown theory for explaining anti-busing movement support and participation. Displayed in Table 2 are the correlations between the three measures of solidarity and the dependent variables. The positive signs associated with the correlation coefficients in the first two rows indicate that respondents scoring high on the community attachment scale and on the secondary group participation scale tend to support and participate in the anti-busing movement. These findings favor the solidarity model over the mass society model. Also, the magnitude of the correlations are, in several instances, substantial. Community attachment, for example, explains 25% of the SUPPORT variance, while secondary group activity explains 11% of the variance of PARTICIPATE.

Table 2. Correlations among Community Attachment, Secondary Group Participation, Primary Group Participation and SUPPORT and PARTICIPATE; Partial Correlations among Community Attachment, Secondary Group Participation, Primary Group Participation and SUPPORT and PARTICIPATE, Controlling for Education

	SUPPORT	PARTICIPATE
Zero-Order Correlations		
1. Community Attachment	.502**	.359**
2. Secondary Group Participation	.165**	.327**
3. Primary Group Participation	−.112**	−.088*
Partial Correlations (controlling for education)		
4. Community Attachment	.465**	.322**
5. Secondary Group Participation	.299**	.390**
6. Primary Group Participation	.024	−.011

Note: Double starred and single starred entries are significant at the .01 and .05 levels, respectively. Nonstarred entries are insignificant at the .05 level.

More ambiguous is the meaning of the correlation between primary group participation and the two dependent variables (row 3). The negative direction of the correlations indicates support for mass society theory. The correlations are small, however, explaining no more than 1% of the variance of either dependent variable.

We next control the relationship between the three solidarity variables and the dependent variables with a measure of social class, education.[10] We control for social class because previous research has demonstrated that participation in organizational activities and social class covary positively (Verba and Nie, 1972), and the Boston data indicate that support of and participation in the anti-busing movement and social class covary negatively.[11] Thus, social class may operate as a "suppressor" variable on the relationship between secondary group participation and the dependent variables. The data presented in row 5 of Table 2 bear out this expectation. Controlling for education increases the correlation between secondary group participation and SUPPORT and PARTICIPATE from .165 to .200 and from .327 to .390, respectively.

---

[10] Controlling for two additional measures of social class, family income, and head of household's occupation has virtually no effect on the resulting partial correlations. These data are not presented here.

[11] The correlations between respondents' education and SUPPORT and PARTICIPATE are −.472 and −.273, respectively.

Also of theoretical significance is the effect of controlling for education on the relationship between primary group participation and the two dependent variables (row 6). When education is controlled, the resulting partial correlations between primary group participation and the dependent variables are not significantly different from zero. Thus, the zero-order negative association between primary group solidarity and the dependent variables is a spurious product of their joint dependence on education.

In sum, the evidence clearly undercuts a mass society explanation of anti-busing movement support and participation. Respondents scoring high on the scale measuring community attachment and secondary group participation were more, rather than less, likely to join and support the anti-busing movement. Furthermore, controlling for education increases substantially the correlations between secondary group participation and the two dependent variables. This finding is especially damaging to the mass society model, since that theory stresses the role of secondary organizations in inhibiting social movement participation. Controlling for social class also reveals that the negative zero-order correlation between primary group participation and anti-busing movement support and participation are spurious. Thus, whatever little support existed for mass society theory in the initial set of correlations cannot be considered genuine.

The positive correlations between community attachment and secondary group participation and the two dependent variables demonstrate that social cohesion facilitates, rather than inhibits, support and participation in this protest movement. According to solidarity theory, community attachment increases protest participation by providing citizens with a set of shared symbols, community pride, and other conditions that facilitate the mobilization process.

Why does primary group participation, in contrast to secondary group participation, fail to correlate with anti-busing movement support and participation? One plausible explanation is that the poor quality of the primary group participation scale results in its low correlation with the dependent variable. Given the limitation of the data, however, we cannot test this explanation.

A more substantive explanation for the differing correlations between the dependent variables and primary group participation and secondary group participation can be derived from solidarity theory. As noted above, solidarity theorists argue that one way in which solidarity increases protest participation is by making bloc mobilization possible. The recruitment of entire blocs of previously organized individuals, solidarity theorists hypothesize, greatly facilitates the mobilization process. Given the informal nature of most primary groups in American society, however, it is unlikely that primary groups would provide a basis of bloc mobilization. Thus, an individual scoring high on the primary group participation scale is no more likely than a low scorer on the scale to be subject to bloc mobilization.

That at least several secondary organizations did function as bases for bloc mobilization is supported by historical evidence. For example, many of the anti-busing movement leaders were active in Home and School Associations, a predominantly white parent organization. This link allowed the anti-busers to mobilize several Home and School Associations directly into their movement. The anti-busers also drew into their movement several preexisting civic associations, such as the West Roxbury Residents Association and the South Boston Action Council. Thus, the bloc mobilization of secondary groups, but not of primary groups, appears to account for their differing correlations with the dependent variables.

3. Solidarity Model versus Discontent Model

In this section we will first assess the discontent theorists' argument—that grievances are a significant cause of protest support and participation—by examining the relative deprivation version of discontent theory. Second, we will examine the breakdown theorists' assumption that social disorganization increases discontent.

Relative deprivation here refers to the feeling that one is deprived of a desired object, in comparison to other persons not being deprived of it.[12] We will describe individuals as experiencing "opportunity relative deprivation" if they feel the system provides the opportunities to acquire a desired goal to other individuals or groups, but not to them or their group. "Outcome relative deprivation," on the other hand, arises when individuals feel the rewards they are receiving, such as income, are too few, compared to those received by others.

The existence of two bases for opposition to affirmative action programs illustrates this distinction. Some argue that they unfairly deprive whites of the opportunity to acquire a particular benefit. Others, in contrast, assert that these programs grant blacks a disproportionate amount of the social benefit at hand.

An opportunity relative deprivation scale was built from the responses to two questions:

> I will now read some statements about current issues and relations between the races. Please tell me whether you strongly agree, mildly agree, mildly disagree, or strongly disagree with the following statements. . . .
>
> Many of the government's policies designed to help blacks are a form of unfair "reverse discrimination" against whites.
>
> Irish, Italian, Jewish and many other immigrants overcame prejudice and worked their way up. Blacks should do the same without any special favoritism.

The response from two sets of questions are combined to form an index of outcome relative deprivation. First, respondents were asked to evaluate how well various groups and they themselves had fared economically over the past several years. An introductory statement read:

> Now we'd like your opinion about the economic gains and losses made by different groups over the past 5 years. (HAND CARD D) Suppose those groups which have gained a great deal economically over the past 5 years are at the top of the scale—at point number plus 3. And suppose the groups which have lost a great deal economically over the past 5 years are at the bottom of the scale—at point number minus 3. The middle of the scale, zero, represents groups which have neither gained nor lost over the past 5 years. Where would you place (people in your neighborhood, blue-collar workers, white-collar workers, professionals, black people in general, people in the suburbs outside of Boston, and you yourself) on this scale?

A second set of questions asked the respondents if they thought these same groups were getting their just economic rewards. The question read:

> Next we'd like to know if you think these groups are now getting economically what they deserve—that is, what is fair. (HAND CARD E) All things considered, do you think (people in your neighborhood, etc.) get more than they are entitled to, just what they are entitled to, or less than they are entitled to?

---

[12] Analysts have defined relative deprivation in two substantially different ways. According to one tradition, relative deprivation occurs when individuals perceive a discrepancy between their goals and their current or anticipated level of achievement. The larger the gap between persons' situation and their desired level of achievement, the more likely are they to become involved in a social movement (Gurr, 1970:13; Feierabend et al., 1969). This tradition of research is based on the frustration/aggression theory in psychology (Gurr, 1970:9). Stated simply, the frustration/aggression theory holds that frustrated individuals will tend to act aggressively toward the perceived source of frustration (Berkowitz, 1962). The same psychological mechanism that links frustration to aggression, according to these researchers, also links relative deprivation to political protest and violence.

Drawing on reference group theory, analysts in a second tradition maintain that relative deprivation occurs when persons feel that their own or their group's lot compares unfavorably and unjustly with the situation of other individuals or groups. This definition emphasizes group comparisons and standards of justice (Runciman, 1966; Vanneman and Pettigrew, 1972).

We use the second definition for two reasons. First, social movements are basically attempts to alter or preserve group or "structural" relationships. Thus, the relevant evaluation is whether people feel that the current group relationships operate in their favor or not (Vanneman and Pettigrew, 1972:482). Second, people can feel that the current group relationships fail to operate in their favor and also feel that such a situation is justified and proper. Thus, feelings of deprivation in comparison to others will motivate protest only when that comparison offends people's sense of justice (Moore, 1978:49–116).

Table 3. Stepwise Multiple Regression among Relative Deprivation Variables and SUPPORT and PARTICIPATE

	Simple R	Multiple R	R^2 Change
Relative Deprivation Variables		SUPPORT	
1. Opportunity relative deprivation	.537	.537	.289
2. Neighbors versus blacks	.423	.572	.039
3. Self versus professionals	.285	.586	.015
Relative Deprivation Variables		PARTICIPATE	
4. Self versus blacks	.335	.335	.112
5. Opportunity relative deprivation	.329	.388	.038
6. Whites versus professionals	.298	.426	.031

We derived measures of outcome relative deprivation in the following way: a respondent's score on white/black relative deprivation, for example, is computed by subtracting his/her scores on the two questions about whites from his/her scores on the two questions about blacks, and then combining the two remainders.

Displayed in Table 3 are the results of a stepwise multiple regression equation which included both outcome and opportunity relative deprivation measures. Excluded from further consideration are the outcome relative deprivation measures which produced an increment in R^2 that was smaller than .01 and statistically insignificant at the .05 level. The simple correlations displayed in column 1 of Table 3 show that both a measure of opportunity relative deprivation and several measures of outcome relative deprivation are strongly to moderately related to protest support and participation. Opportunity relative deprivation, for example, explains 29% of the variance of SUPPORT and 15% of the variance of PARTICIPATE. Similarly, the respondents' comparisons between the economic situation of their neighbors with that of blacks "explains" 18% of the variance of PARTICIPATE.

In addition, the R^2 change in column 3 shows that both opportunity and outcome relative deprivation contribute separately to the explained variance of each dependent variable. Finally, the multiple correlations displayed in rows 3 and 6 undercut the solidarity theorists' argument that feelings of deprivation are not a significant cause of protest support and participation. Relative deprivation explained 34% of the variance of SUPPORT and 18% of the variance of PARTICIPATE. Thus, the data support the hypothesis that if a person feels deprived relative to members of another group, s/he is likely to support or join a protest movement.

It should be noted, however, that the data are also consistent with an alternative explanation. Some Boston residents may have become involved in the anti-busing movement for reasons unrelated to relative deprivation. Once they joined, intense exposure to the anti-busing movement's ideology may have bred feelings of relative deprivation. Longitudinal (panel) data are required to test these conflicting explanations.

4. *Disorganization and Discontent*

In this section, we test the breakdown theorists' hypothesis that disorganization breeds discontent (see Figure 1, part 1B). The first step in the analysis is to reduce the number of relative deprivation and solidarity variables, so as to simplify and facilitate the statistical analysis. In the previous section we used stepwise multiple correlation to isolate the five "best" measures for predicting anti-busing movement support and participation. We can construct an index which summarizes the respondents' scores on each of these relative deprivation variables. The "New RD" index is defined as the number of times each respondent scores among the most deprived fifth on each of the relative deprivation measures.[13]

---

[13] Cronbach's alpha for the New RD scale is high (.819). The correlations of the New RD variables with the dependent variables are .477 and .405. These correlations are not much lower than the multiple correlations of all the relative deprivation variables used to make up the New RD scale. This indicates that the New RD variable successfully sum-

We will retain as separate variables both the community attachment scale and the secondary group participation scale. The primary group participation scale will be excluded from further consideration, however, because of its low correlation with the dependent variables.

Table 4 displays the correlations between the solidarity variables and the New RD scale. The positive correlation between the New RD scale and community attachment (r = .282) and secondary group participation (r = .114) means that respondents scoring high on the New RD scale tend also to score high on the two solidarity scales. This finding is of considerable theoretical interest, since it contradicts the breakdown theorists' hypothesis that social disorganization increases the level of discontent. Although the correlations between relative deprivation and the solidarity indices are only moderately large, they indicate that solidarity, not disorganization, breeds discontent.

We can speculate why relative deprivation is a positive function of solidarity. Strong community attachment and high rates of group participation increase an individual's awareness of and concern for others in his or her community. The level of discontent of such an individual would be affected by both grievance-producing events against him or her and grievance-producing events against others in his or her community. Thus, solidarity increases discontent by multiplying the effects of grievance-producing events.

In sum, one version of the breakdown model has two steps: disorganization → discontent → protest. While the Boston data support the second step in the model, they undercut the first step.

5. *Separate Effects of Solidarity and Relative Deprivation*

The additional finding that relative deprivation and solidarity covary, however, raises the possibility that the correlation between relative deprivation and the dependent variables are spurious products of their joint dependence on solidarity. The coefficients in Table 5 reveal the extent to which this is the case. Displayed in row one of the table are the zero-order correlations between New RD (relative deprivation) and the dependent variables. Row three of the same table shows the partial correlations between New RD and the two dependent variables, while controlling for the two solidarity variables. Other data in Table 5 allow us to assess the extent to which the solidarity variables and the dependent variables correlate because of their joint dependence on solidarity. Row two of the table shows the multiple correlation between the two solidarity variables and the dependent variables. Finally, displayed in row four of Table 5 are the multiple-partial correlations between the two solidarity variables and the dependent variables, while we control for New RD.

Table 4. Correlations between Community Attachment and Secondary Group Participation and Relative Deprivation

	Relative Deprivation
1. Community Attachment	.282
2. Secondary Group Participation	.114

Note: Both entries are significant at the .01 level.

Table 5. Correlations, Multiple Correlations, Partial Correlations, and Multiple Partial Correlations among New RD, Neighborhood Solidarity, Secondary Group Solidarity, SUPPORT and PARTICIPATE

	SUPPORT	PARTICIPATE
1. New RD	.435	.403
2. Multiple Correlation, Community Attachment and Secondary Group Participation	.506	.437
3. Partial Correlation, New RD Controlling for Community Attachment and Secondary Group Participation	.351	.334
4. Multiple Partial Correlation, Community Attachment and Secondary Group Participation Controlling for New RD	.439	.279

Note: All entries are significant at the .01 level.

---

marizes the information contained in each of the five relative deprivation variables used to make up the scale.

Comparison of the coefficients in rows one and three of Table 5 reveals that controlling for the two solidarity variables reduced the correlations between relative deprivation and SUPPORT and PARTICIPATE, from .435 to .351 and from .403 to :334, respectively. This indicates that the influence of relative deprivation on the dependent variables is moderately diminished if the confounding effects of the solidarity variables are removed. Each of the partial correlations, however, is moderately strong and statistically significant at the .01 level.

Similarly, comparison of the coefficients in rows two and four of Table 5 shows that controlling for the New RD variable reduces the multiple correlation between the two community solidarity variables and SUPPORT and PARTICIPATE from .506 to .439 and from .406 to .395, respectively. Again, the partial correlations are moderately strong and statistically significant at the .01 level.

In sum, the strength of the four partial correlations in rows four and five of Table 5 suggests that the relationship between discontent, solidarity, and the dependent variables is genuine. These partial correlations are the strongest evidence presented that both relative deprivation and solidarity contribute separately to the variation in anti-busing movement support and participation.

6. *Conclusion*

This paper has examined the reasons for popular participation in the Boston anti-busing movement. The analysis has several implications for the theoretical issues presented at the outset.

The Boston data provide no support for the mass society model. Isolated individuals were less, not more, likely than others to become involved in the anti-busing movement. The evidence instead supports the solidarity theorists' contention that mobilization will not take place unless the conditions normally associated with solidarity are present. Apparently, Boston's neighborhood organization and the residents' strong attachment to their community provided some of those conditions. In addition, historical evidence supports the solidarity theorists' hypothesis that bloc recruitment facilitates mobilization.

The Boston data, however, fail to sustain the solidarity theorists' further argument that discontent plays an insignificant role in accounting for protest. Both solidarity and a form of discontent, relative deprivation, contributed separately and substantially to the variation in anti-busing movement support and participation. This conclusion is tentative, however, since we were unable to establish the extent to which relative deprivation was a product, rather than a cause, of participation in the anti-busing movement. Nevertheless, these findings suggest that the fundamental problem with the solidarity theorists' argument is its premise that "discontent is ever-present for deprived groups" (Jenkins and Perrow, 1977:251). This premise requires empirical proof, and to date no solidarity theorist has seriously attempted to provide the requisite evidence. Indeed, solidarity theorist Anthony Oberschall (1978:298) expresses the premise so ambivalently as to call into question his own commitment to it: "[g]rievances and disaffection are a fairly permanent and recurring [*sic*] feature of the historical landscape." More significantly, carefully conducted research by Moore (1978) indicates that even the most extremely deprived groups do not always experience discontent. Moore's (1978) study shows that some inmates of Nazi concentration camps perceived their suffering to be unjust or morally wrong. Thus, Moore's research as well as the Boston data do not support those solidarity theorists who argue that one should assume, a priori (Jenkins and Perrow, 1977:250), that fluctuations in discontent cannot account for protest.

While the finding (that discontent and protest covary) undercuts the solidarity argument, the Boston data also fail to support the breakdown contention that discontent is the product of social disorganization. Disorganization and discontent were inversely, not directly, correlated. This finding suggests that discontent is generated by social organization and group solidarity.

The finding that disorganization and discontent are inversely related suggests an additional weakness in the breakdown model. Not only are isolated individuals without the resources to engage in protest, as the solidarity theorists would argue, but isolated individuals are also less likely to experience relative deprivation sufficient to motivate protest.

Researchers have traditionally confined their analysis to the consquences of outcome relative deprivation, ignoring the implications of opportunity relative deprivation. Thus, our finding that both opportunity relative deprivation and outcome relative deprivation are separately and substantially related to protest has practical as well as theoretical implications. The belief of whites that they are being deprived of opportunities in favor of blacks may have an independent political impact in other social contexts. Feelings of opportunity relative deprivation may motivate, for example, protest against government and private programs designed to increase opportunities for blacks.

Our analysis of popular involvement in the Boston anti-busing movement leads us to conclude that both the breakdown and solidarity theories help to explain protest. That several different theories helped explain a single phenomenon suggests a need for an integrated theory based on insights from the different models.

ISSUES IN THE COMPARATIVE MEASUREMENT OF POLITICAL DEMOCRACY*

KENNETH A. BOLLEN**
Brown University

American Sociological Review 1980, Vol. 45 (June:370–390)

The empirical study of the causes and consequences of political democracy has been the subject of considerable research. Yet cumulative development of this research is hampered by the controversial aspects and limitations of the existing indices of political democracy. These issues concern the validity of the indicators, the unknown reliability, and the limited sample and temporal coverage of these indices. After a discussion of these issues, a revised index of political democracy that overcomes some of these limitations is presented. The indicators of the revised index are analyzed by means of confirmatory factor analysis and the reliability of the measure is discussed. The index is generally better than existing measures in reliability, sample size, and temporal coverage; but the remaining limitations of the index are reviewed. The moderate to high correlations of this index with other democracy indices support its external validity. Yet, the differences in empirical results possible by using different indices are demonstrated. Finally, there are two appendices. The first provides the technical details of the confirmatory factor analysis. The second appendix lists the values of the political democracy index.

For over two decades, political democracy has been an important variable in quantitative, cross-national research (e.g., Lerner, 1958; Neubauer, 1967; Stack, 1978). Increasingly, many researchers view political democracy as a luxury that can be ill-afforded by Less Developed Countries (LDCs) facing the more pressing problems of socioeconomic development, income inequality, and rapid population growth. Yet, despite the shift in research to these other problems, political democracy has remained of interest because of its hypothesized impact upon (and relationship with) development, distribution, and population growth. For instance, a number of researchers suggest that political democracy is an obstacle to economic development. Others argue that the policies needed to reduce rapid population growth in the Third World are not possible in a democratic framework (e.g., Heilbroner, 1974). These and other hypotheses remain largely untested.

A researcher wishing to test these hypotheses faces a number of difficulties. One central problem is the controversy surrounding the measurement of political democracy (e.g., Cutright, 1968; Neubauer, 1968; May, 1973). These measurement problems can drastically affect empirical results. An illustration of this is the recent research on the impact of political democracy on income inequality. The findings of these studies are often contradictory. For instance, Cutright (1967) finds that political democracy reduces income inequality, while Jackman (1975) finds no effect once economic development is controlled. Hewitt (1977:460) concludes that it is "plausible to assume that the apparent relationship between democracy and equality is indeed a spurious one." On the other hand, Stack (1978) finds that democratic performance reduces income inequality even after controls for economic development and dependency. Jackman (1975:86–7), Hewitt (1977:456), and Stack (1979:168–9) argue that the primary reason for these contradictory findings is the difference among the measures of political democracy which are used.

Although many researchers have called attention to the importance of proper measurement instruments and the large degree of measurment error in cross-national variables, papers mainly devoted

to developing valid and reliable cross-national indices are rare. The cost of this neglect is the variety of results that characterizes, for example, the democracy-inequality findings. Similar diversity will accompany other analyses of the causes and consequences of political democracy until some of these measurement issues are addressed. Thus, the cumulative development of research in this area dictates that greater attention be given to the measurement of political democracy (Lenski, 1976).

There are several purposes of this paper. First, the controversial aspects and limitations of the commonly used indices of democracy are discussed. These issues concern the validity of the indicators, the absence of any discussion of reliability, and the limited sample and temporal coverage of these indices. A second purpose is to present a revised index that overcomes some of these limitations. The indicators of the revised index are analyzed by means of confirmatory factor analysis, and the reliability of the measure is discussed. That index is generally better than existing indices in reliability, sample size, and temporal coverage. The correlation of this revised measure with the other democracy indices is calculated as a means of external validation. The differences in empirical results, made possible by using different indices, are demonstrated. Finally, to facilitate future research and to allow critical evaluation, an appendix lists the revised political democracy index for 123 countries in 1965, and 113 in 1960.

A Theoretical Definition of Political Democracy

A theoretical definition of political democracy is a prerequisite to evaluating the validity of past indices and in choosing indicators for a revised index. The theoretical definition is necessary to establish a standard by which the indicators may be evaluated. Much debate surrounds the definition of democracy and it is not possible to resolve the dispute, here. But it is possible and necessary to "outline" a definition which is used to guide the research in this paper.

As de Schweinitz (1964:13) observed:

> Democracy is one of those troublesome words which means all things to all people. Like motherhood and patriotism, it is thought to be a noble condition and is evoked by politicians, publicists, preachers, and demogogues to prove their unsullied intentions and just claim to popular support.

Today, one need only look at the various nations in the world which consider themselves democracies. It is clear that the various "People's Democracies" (e.g., East Germany) have a form of government which many persons living in market economy nations (e.g., the United States) do not consider democratic. Likewise, the "Bourgeois Democracies" existing in capitalist economies are not considered true democracies by the People's Democracies.

In the social sciences, a number of definitions of political democracy have come into use. Several of the more common definitions are discussed here. Lipset (1963:27) defines democracy as

> a political system which supplies regular constitutional opportunities for changing the governing officials, and a social mechanism which permits the largest possible part of the population to influence major decisions by choosing among contenders for political office.

Lipset's definition places a heavy emphasis on elections to choose representatives that hold political office.

Dahl (1956:67–90), like Lipset, emphasizes electoral processes in his definition of democracy. He also suggests a number of more specific criteria to evaluate whether or not the elections are democratic. For instance, Dahl suggests, among other things, that a democracy should have elections in which each vote is weighted equally, each individual possesses identical information about the alternatives presented for decision, and the orders of elected officials are executed.

Downs (1957:23–4) states that a democratic society must have periodic elections, decided by majority rule, in which each voter casts only one vote. In addition, he suggests that there must be two or more parties competing for control, and a single party (or coalitions of parties) chosen to run the government. Lenski

(1966:319) identifies democratic political systems not only by the extent of the electoral franchise but also by the existence of political liberties, which preserve the right of organized political opposition.

A second group of writers has focused, not on the existence of fair elections and political liberties but, instead, on the existence of political elites. Mosca (1939), Michels (1962), and Mills (1956), among others, have argued that in all nations there exists a group which holds a disproportionate degree of political power. Michels formulated his "iron law of oligarchy" in the belief that it is functionally necessary for power to be centered, eventually, in an elite of any organization or society. Similarly, Bachrach (1967:1) argues: "the exigencies of life in the industrial and nuclear age necessitate that key and crucial political decisions in a democracy, as in a totalitarian society be made by a handful of men."

It is true that the premier, president, or dictator all possess far more control over a nation's decisions than do the masses of the population. Theorists of political elites infer from this observation little variation across societies in the concentration of political power. Yet it does not necessarily follow that the political power of the elite, relative to that of the nonelite, is the same in each country.

In some countries the political system may allow for a stronger elite than in other countries. In Spain during Franco's rule, for instance, political power was far more concentrated than in Britain or Canada. Similarly, the elites of Saudi Arabia hold more political power than the elites of Australia. The important point to recognize is that the political power of the elite, relative to the nonelite, differs from nation to nation.

It is these *differences* in the political power held by the elite, relative to the nonelite, that helps identify how democratic a nation is. I define *political democracy* as *the extent to which the political power of the elite is minimized and that of the nonelite is maximized.* Identifying these differences in political power is extremely difficult. The major difficulty is that there is no widely accepted unit of measure for political power. Unlike in a study of the distribution of income, the number of "dollar-like" units of political power held by the various groups in a country cannot be evaluated. The approach to measurement, in this case, must be more indirect. The definitions of Lipset, Dahl, Downs, and Lenski discussed earlier provide some help in deriving these indirect measures. In particular they call our attention to elections and political liberties which may increase the political power of the nonelite.

There are a number of characteristics that determine whether elections bring political power to the nonelite. For example, the elections should be fair, allow some choice from among alternative candidates or policies, and allow a universal franchise. In addition, the results of the election must be binding on all parties. In nations where these and other conditions (e.g., the equal weighting of voting) are met, the nonelites have more political power over elites and their policies than in nations where no elections, or only rigged ones, occur. Popular sovereignty as represented in electoral processes is not enough. A nonelite should also possess political liberties.

Political liberties refer to the rights of all individuals and groups to protest or support—freely—government policies or decisions. As such, political liberties provide additional political power for the nonelite, allowing them to organize opposition to the elites and their policies. A population possessing free speech, a free press, and freedom of opposition has a greater potential for influencing the decisions of elites than does a country where these liberties do not exist. These political liberties also allow the formation of interest groups and participation in political parties that can compete with—and possibly replace—the existing elites. In countries where political meetings are not allowed, one or more parties are banned, or the press is censored, the nonelites' political power is reduced, and the political power of the elite is more secure.

It is sometimes thought that definitions of political democracy, as just discussed, are largely definitions of bourgeois democracy. This criticism assumes that these definitions lead to measures which uniformly rank capitalist societies as highly democratic, and socialist or communist countries as nondemocratic. However, the degree of political liberties and popular sovereignty (as represented in elections) varies both between and within capitalist, communist, and socialist nations. For instance, using these two criteria, Yugoslavia exhibits a higher level of political democracy than the Soviet Union or Albania, even though all three are communist countries. Similarly, the two criteria provide a ranking of differences in political democracy in capitalist countries. Canada, for instance, is more democratic than other capitalist countries such as Portugal or Honduras.

This definition of political democracy also shows that a communist or socialist country may be more democratic than a capitalist one. For example, in the mid-'60s Yugoslavia was more democratic, politically, than capitalist countries such as Taiwan and Spain. Furthermore, many of the Scandinavian countries with a socialist orientation are at higher levels of political democracy than are a number of capitalist nations. Thus, this definition, when evaluating the level of political democracy, does not consider the type of economic system of a country.

Previous Measures of Political Democracy

A variety of indicators appears in political democracy indices. Many of these indicators closely correspond to the theoretical definitions of political democracy. Others, however, are of questionable validity. Some of the indicators are measures of political characteristics that may occur in either democratic or nondemocratic political systems. Two such indicators are those measuring voter participation (or turnout) and political stability. These are not the only indicators with questionable validity, but these two are widely used in political democracy indices and deserve special attention.

The use of the percentage of the population voting in national elections as a measure of political democracy has a relatively long history. In his classic study, Lerner (1958) measures the level of political democracy by the percentage of the population voting in national elections. Voting-participation statistics are also in the democracy measures of Smith (1969), Jackman (1973; 1975), Coulter (1975), and Stack (1979).

There are several potentially valuable aspects of voter participation as an indicator of political democracy. First, political-participation statistics may provide a rough indicator of the extent of the national franchise, which is an important aspect of popular sovereignty.[1] Second, high political participation may lead to elected officials who are more representative of the class structure of the general population[2] (Wences, 1969; Stack, 1979). Finally, voter turnout measures the degree to which citizens play an active role in the political system (Stack, 1979).

Despite the potential usefulness of participation statistics, these statistics are confounded with many other factors, some of which are only marginally related to political democracy. Lerner (1958:68) discusses how, in some countries, voter participation is a *symbol* of political democracy often used in nondemocratic nations. Huntington (1968:89) argues: "Popular participation in politics does not necessarily mean popular control of government. Constitutional democracies and communist dictatorships are both participant polities." Similarly, Kornhauser (1959) states that voting participation is considered desirable and is encouraged in both democratic and authoritarian countries.[3] Furthermore, in a number of countries, all eligible voters are legally obligated to vote (e.g., Ecuador, *circa* 1960). In these nations, high participation does not indicate widespread political power in the nonelite. In fact, since the political elite is largely responsible for the laws of mandatory participation, the high voting turnout may indicate that the elite has considerable political power, relative to the nonelite.

---

[1] This is not true if voter turnout is expressed as a percentage of the electorate rather than of the total adult population.

[2] See Hewitt (1979) for a criticism of this assumption.

[3] Note that according to Taylor and Hudson (1972:Table 2.8), the ten countries with the greatest voter turnout are: Albania, North Korea, Soviet Union, Romania, Bulgaria, Ivory Coast, Guinea, Czechoslovakia, Gabon, and East Germany. Very few researchers would consider any of these countries as highly democratic.

An additional problem with voter participation is the ambiguous meaning of high- and low-turnout levels even when there is a universal franchise. Lipset (1963) suggests that a low level of participation may indicate that the people's will is expressed in government policy, so that there is no need for participation. That is, low participation may indicate at least partial satisfaction with the government. However, in some situations, low participation indicates not satisfaction but, rather, the apathy of the masses who feel alienated from their government. In these situations, the vote may be viewed as an ineffective tool for bringing about governmental change. In either case, these arguments suggest that voter turnout does not necessarily indicate the level of political democracy.

Furthermore, the doubtful validity of voter participation may be shown empirically. Evidence against voter turnout as a measure of political democracy is the low correlations it has with other indicators of democracy. For instance, the percentage of the over-20 population voting correlates −0.49 (N = 45) with Lowenstein's (1967) freedom of the press index and −0.28 (N = 52) with the fairness of elections (source of data: Taylor and Hudson, 1971). Voter turnout correlates 0.09 (n = 19) with Coleman's (1960) measure of the democracy in LDCs.[4]

Given the theoretical and empirical arguments against using voter turnout as a measure of political democracy, participation statistics should not be used in political democracy indices (see, also, May, 1973:14–5). This is not to deny the importance that political participation has as a concept, in its own right, but it does question the assumed equivalence of political democracy and participation.

A second component often built into political democracy indices is political stability. Frequently, countries are scored not only on the extent of political democracy but also on the stability of the political system. For instance, an early attempt at measuring political democracy classified European countries as democratic if they had had an "uninterrupted continuation of political democracy since WWI" and classified Latin American countries as democratic if they had had "a history of more or less free elections for most of the post-WWI period" (Lipset, 1959:74).[5] Other political democracy indices which incorporate measures of stability include Cutright (1963), Cutright and Wiley (1969), Smith (1969), Coulter (1975), and Hewitt (1977).

The most frequently used index is Cutright's (1963).[6] This measure (or variations of it) is used in many empirical studies of political democracy (e.g., McCrone and Cnudde, 1967; Smith, 1969; Coulter, 1975; Rubinson and Quinlan, 1977). Since this measure is widely used, it provides a good example of how political stability is incorporated into indices of political democracy. Thus, a brief description of its construction is instructive.

The time period covered by Cutright's (1963) index is 1940 to 1960. For each year, the legislative and executive branches of government are assigned a score. The highest score is assigned to each country having a parliament or legislative body that has representatives of two or more political parties, with the minority party holding at least 30% of those seats, and a chief executive who is in office through an open election. The score a nation receives for each year from 1940 to 1960 is summed to form the final index. As noted by Cutright (p. 256), this scoring technique penalizes a country for political instability and rewards it for stability.

---

[4] Even if all Communist countries are dropped, the correlation of voter turnout with press freedom is only 0.25 (N = 37) and with fairness of elections is 0.05 (N = 44), neither of which is significant at the 0.05 level. These results parallel those of Coulter (1975). Coulter constructs a democracy index of three components: competitiveness, liberties, and participation. Although he finds that liberties and competitiveness correlate 0.71, participation correlates 0.20 with competitiveness and 0.19 with liberties.

[5] As Jackman (1975:86) notes, Fox and Miller (1965) use Lipset's measure but refer to it as a measure of "political stability."

[6] Although commonly used as an index of democracy, Cutright (1963; 1968) claims that it actually measures political development. However, in later publications, Cutright refers to a very similar measure as a political representation index.

Combining measures of stability with measures of political democracy causes several difficulties. One practical problem is that of studying changes in political democracy. A stability/democracy measure is often aggregated over a ten- or twenty-year period. This degree of temporal aggregation may "average-out" many important changes in political democracy that occur. For instance, a country may alternate from a highly democratic to a nondemocratic system within a short time span. A measure aggregated over a number of years will show the average of these extremes and will, therefore, score it as moderately democratic—even though it never was moderate during this period.

An even more serious problem of using indices that combine political stability and democracy is that the results of analyses using such indices are ambiguous. This is because it is not known whether the discovered relationship is to stability, to democracy, or to some combination of the two. For instance, Cutright's (1967) analysis of the effect of political democracy on income inequality showed a significant positive effect. But, Jackman (1975:86) claims that it is not the political democracy component—but, rather, the stability component of Cutright's measure—that leads to this relationship. This ambiguity can also be expected in other cases where an index that confounds political democracy and stability is used. Thus, researchers should proceed by treating political stability as analytically and empirically separate from the concept of political democracy. Although these variables may be positively related, they are not one and the same. These arguments will be demonstrated empirically later in this article.

A Revised Index of Political Democracy

The previous sections of this article demonstrate the need for a revised index of political democracy that corresponds more closely to the theoretical definitions of the concept. In addition, indicators of voter turnout and political stability were shown to represent concepts separate and distinct from political democracy and not, therefore, properly used in democracy indices. This section of the article presents a revised political democracy index.

In the theoretical definition of political democracy, the two most important aspects were political liberties and popular sovereignty (as represented in electoral processes). Most characteristics attributed to political democracy may be classified under one or the other of these two general concepts. For instance, the fairness of elections, the proportion of the most important government positions that are elected rather than appointed, and the type of electoral system (proportionate vs. other) are indicators of popular sovereignty. The extents of free speech, free press, and the freedom to organize opposition parties or groups are indicators of political liberties. Thus, at a minimum, a measure of political democracy should include indicators of both political liberties and of popular sovereignty.

The revised index of political democracy (hereafter, POLDEM) has indicators of both of these concepts. Table 1 lists these indicators, their sources, and several technical notes on their use. A brief description of these measures follows. A more detailed description is in the original sources and in Bollen (1979).

The three indicators of political liberties are: (1) press freedom, (2) freedom of group opposition, and (3) government sanctions. Freedom of the press is ranked on a nine-point scale that measures the degree of control normally exercised by any official agency which has the power to interfere with the dissemination and discussion of the news (Nixon, 1960:17). Freedom of group opposition measures the degree to which organized opposition is allowed. It is scored on a four-point scale, ranging from a low of no parties or all but dominant party and its satellites excluded, to a high of no parties excluded.

The third indicator of political liberties is government sanctions. Government sanctions are actions taken by the government which curtail the political activities of one or more groups of the population. The sanctions include censorship of

Table 1. Six Components of the 1965 and 1960 Revised Index of Political Democracy

Variable	Symbol	Source	Notes
Press Freedom	Y_1	Nixon (1965; 1960)	—
Freedom of Group Opposition	Y_2	Banks (1971: segment 10, field o)	1
Government Sanctions	Y_3	Taylor and Hudson (1971)	1
Fairness of Elections	Y_4	Taylor and Hudson (1971)	2
Executive Selection	Y_5	Banks (1971: segment 2, field j)	1, 2, 3, 4
Legislative Selection	Y_6	Banks (1971: segment 2, field p; segment 10, field l)	1, 2, 4

Notes:

1. For Y_2, Y_3, Y_5, and Y_6, the average scores for 1964–1966 and 1959–1961 are used for the 1965 and 1960 measures, respectively. If the indicators are not available for the full three-year period, the average scores, over those years with data, are used.
2. If no elections were held from 1956–1964 (or 1961–1967) a country is scored zero for 1960 (or 1965) on variables Y_4-Y_6. Election information is from Taylor and Hudson (1971; 1972). No election information after 1967 is available from this source.
3. The "indirect election" category of Banks is combined with the "elective."
4. Trinidad and Tobago, Jamaica, and Uganda's 1960 rank, on Y_5 and Y_6, are derived from 1962 data, because earlier data are not available.

the mass media, instituting a curfew, banning or harassing political parties, and the arrest of opposition party members. This indicator is based on the number of such events.[7]

The three measures of popular sovereignty, as listed in Table 1, are: (1) fairness of elections, (2) executive selection, and (3) legislative selection. Fairness of elections scales the degree to which elections are relatively free from corruption and coercion. The scoring of this variable is based on whether or not alternative choices exist, and on whether or not the elections are administered by a nonpartisan administration. Also considered are whether or not the elections are rigged and if the results of the elections are binding on all parties. The four-point scale ranges from a low of no elections, to a high of relatively free and competitive elections.

The executive selection variable indicates whether the chief executive of a country is elected, or not. The legislative selection variable determines whether the legislative body is elected but, in addition, considers the effectiveness of the legislative body.[8] The lowest score is given to countries with no elections or a nonelective legislative body, while the highest score is given to legislative bodies that are both elected and an effective power in determining national policies.

Each of the six components was linearly transformed to range from a low of 0 to a high of 100.[9] For some countries, not all the indicators were available. In those

---

[7] One difficulty of using government sanction in its original form is that there is a built-in bias against countries with high political liberties to begin with; the greater the freedom, the more negative sanctions the government can impose. In contrast, a country low in political liberties has fewer potential restrictions to impose, because many of these negative sanctions are already in effect. Therefore, the negative government sanction indicator should take into account the degree of political liberties. The correction procedure used is to subtract the number of negative government sanctions from a political liberty score formed by a country's average freedom of the press and group opposition indicators. The correlations of this corrected measure with the five other indicators of the index are higher than when the uncorrected or logged negative sanction variable is used.

[8] The elective/nonelective legislature variable is scored 1 or 0. This is then multiplied by the effectiveness of the legislative body. The scores are multiplied so that, for example, elected "puppet" legislatures do not score as high as those that are both elected and effective, on the assumption that the former are not as important to political democracy as the latter.

[9] The range of the scale, from 0 to 100, is arbitrary. The 0 point does not represent the lowest degree of political democracy possible, nor does 100 represent complete equality. Further reductions or increases in

Table 2. Correlations of Six Components of Political Democracy, 1965 Measures Above the Diagonal (N= 123) and 1960 Measures Below Diagonal (N = 113)

		Y_1	Y_2	Y_3	Y_4	Y_5	Y_6
Press Freedom	(Y_1)	—	0.776	0.852	0.767	0.618	0.739
Freedom of Group Opposition	(Y_2)	0.770	—	0.881	0.704	0.557	0.829
Government Sanctions	(Y_3)	0.788	0.858	—	0.723	0.595	0.776
Fairness of Elections	(Y_4)	0.775	0.649	0.684	—	0.666	0.741
Executive Selection	(Y_5)	0.615	0.544	0.596	0.582	—	0.693
Legislature Selection	(Y_6)	0.765	0.795	0.758	0.695	0.681	—

All correlations significant at 0.001 level.

cases where more than three of the six components were missing, the case was dropped. The nations with one, two, or three components missing have missing values estimated, using least squares procedures.[10] Relatively few values had to be estimated. For example, less than 8% of the values necessary to compute the six components of the 1965 political democracy index needed to be estimated.[11]

Confirmatory Factor Analysis

The correlations between the 1965 and 1960 indicators are presented in Table 2. The correlations for the 1965 indicators are above the main diagonal, and those for the 1960 indicators are below the diagonal. All the correlations are relatively high, as is expected if the indicators are all measuring political democracy.

The hypothesis that the six indicators are measuring a single construct can be evaluated with confirmatory factor analysis. Confirmatory factor analysis allows the researcher to specify the relationship between unmeasured variables and their indicators, and to see if the hypothesized structure is consistent with the data (Jöreskog, 1969; 1974; 1978). In this case, it is hypothesized that the unmeasured variable—political democracy—is "driving" all six measures.

This hypothesis was tested using the covariance matrix of the six components of POLDEM for 1960. Details of the factor analysis are in Appendix 1. Figure 1 is a

---

political democracy are possible for those countries at or near the end points. The countries which score near 100 still have political power concentrated in an elite, and generally the elite underrepresents females and minorities of the country. Limited though it may be, the nonelite in countries that score near the bottom of the index still have some political power.

[10] Four of the predictor variables are from Banks and Textor (1963): freedom of the press, constitutional status of regime, representative character of regime, current electoral system, and freedom of group opposition. A fifth variable used for estimation purposes was Lowenstein's (1967) freedom of the press score as given in Taylor and Hudson (1971). The regression equations used to estimate the individual indicators were usually good predictors. Most had multiple correlation coefficients of 0.85 or over. Conceptually, the variables used to estimate the missing indicators were quite similar to those used in the index. All these factors lead to added confidence in the accuracy of the estimation procedure.

[11] Each country required seven values to compute the index: two for the legislative selection component, and one for each of the remaining five components. Since for 1965 there are 123 countries, the total number of values needed is 123×7 or 861. Less than 8% of these values were estimated. Over half the countries that had any estimated values needed only *one* of the six components estimated.

path diagram of the model with the best fit ($\chi^2_8 = 5.78$, $p = 0.6716$). In conformity with Jöreskog's (e.g., see Jöreskog, 1974) path notation, a circle represents the true unmeasured variable (η = political democracy). The boxes enclose the fallible indicators (Y_i's). The errors of measurement are represented by the ϵ_i's..

The hypothesis that "η has a significant effect on all six indicators" is consistent with the data. However, the initial assumption of independent errors of measurement is not supported (see Appendix 1). As Figure 1 shows, there is a significant positive relationship between the errors of measurement for three of the variables.

This finding is interesting for several reasons. First, virtually all indices used in cross-national research implicitly assume that the errors of measurement of each indicator in an index are independent of the errors of the other indicators. If POLDEM is representative of other cross-national indices, such an assumption may not be warranted. Second, positively correlated measurement errors suggest that a "halo" effect may exist for indicators measured by the same data source. For instance, if there is a positive error in measuring a country on one indicator of a concept, another indicator from the same source may also have a positive error for that country. Finally, the correlated errors of measurement are important because many of the formulas for computing the reliability of an index assume independent errors of measurement. Correlated measurement errors will bias estimates of reliability that do not take it into account (Maxwell, 1968; Werts et al., 1974:31).

For the purpose of this analysis, a reliability formula that allows correlated measurement errors is derived. Defining the reliability as the "true variance" divided by the total variance, the reliability formula is:[12]

$$\text{reliability} = \frac{(\Sigma\lambda_i)^2 \text{ Var }(\eta)}{(\Sigma\lambda_i)^2 \text{ Var }(\eta) + \Sigma \text{ Var }(\epsilon_i) + 2\sum_{i<j}\Sigma \text{ Cov }(\epsilon_i\epsilon_j)} \qquad (1)$$

where i,j = 1,2,. . ., total number of indicators.

The last term of the denominator takes into account the covariance of the errors of measurement. If all errors of measurement are independent, then this term drops out.

The formula is a conservative estimate of the reliability because it uses as a measure of the true variance only that variance associated with η. Indicator-specific variance or variance associated with the correlated errors of measurement is not included in the true variance estimate. This generally will reduce the estimated true variance and reduce the estimated reliability of the index. Thus, if the index is estimated to have high reliability under these restrictive conditions of defining the true variance, then other estimates of reliability that use less restrictive definitions can be expected to be higher.

Formula (1) is used to estimate the reliability of the equal weighted sum[13] of the six indicators that form POLDEM. Substituting the sample estimates of the quantities in (1) from the confirmatory factor analyses, the 1960 and 1965 indices of political democracy have estimated reliabilities of 0.89 and 0.88, respectively.[14] By the usual standards of index construction, this is a high degree of reliability.

Alternatively, a weighted, rather than a simple, sum of the indicators could be used to form POLDEM. There are a number of different ways to derive a weighting scheme, the most popular being those using factor analytic techniques to estimate factor scores. To investigate possible differences between the simple-sum and factor-weighted indices, a regression-based estimate of the factor score was formed. The estimated factor score correlates 0.979 with the simple-sum index. This extremely high correlation between the estimated factor score and the simple-sum suggests that, in terms of practical significance, there is little difference between these two scoring techniques. These results parallel those of Alwin (1973:209–10) who concludes:

---

[12] In a personal correspondence, Jöreskog states that this formula is correct—provided that the congeneric measurement model $Y_i = \lambda_i\eta + \epsilon_i$ holds, with η uncorrelated with all the ϵ_i's. Other reliability estimates using a different definition of true score variance are also possible but are beyond the scope of this article.

[13] The index is formed by POLDEM = $(Y_1 + Y_2 + Y_3 + Y_4 + Y_5 + Y_6)/6$. The simple sum is divided by 6, so that the theoretical range of the index is from 0 to 100.

[14] The estimated error variances for $Y_1 - Y_6$ in 1960 are: 15.02, 55.42, 8.68, 33.87, 107.21, and 37.52, respectively. Results of the 1965 factor analysis are available from the author.

> Until substantial evidence is generated to the contrary perhaps the wisest conclusions with regards to factor score estimation at this point is . . . that they are of no great practical significance owing to their inability to produce meaningfully different results.

There seems, then, to be little reason not to use the simple sum to form POLDEM.

Comparisons with Other Political Democracy Indices

The last section indicated that the Political Democracy Index (POLDEM) has high reliability. This is one important characteristic when choosing any measure for empirical research. But it is clearly not the only one. Practical considerations of choosing a measure for cross-national research include the availability of the measure for as wide or representative a sample and for as many time points as possible.

Table 3 provides a summary comparison of ten measures of democracy. The list is not exhaustive, but it includes some of the most important measures. By far the most commonly used indices are Cutright's (1963) and Jackman's (1973). In fact, Cutright's measurement procedure is part of Smith's (1969), Coulter's (1975), and Cutright and Wiley's (1969) indices. The other indices are not as frequently used by sociologists but should be familiar to researchers in this field of study.

The second column of Table 3 lists the number of countries for which these indices are available. The sample size ranges from a low of 20 for the Fitzgibbon-Johnson Index (Johnson, 1976; 1977) to a high of 123 countries for POLDEM. Smith's index with 110 countries is the

Table 3. Summary Comparison of Measures of Political Democracy

Political Democracy Measure	Sample Size	Reliability	Time Points (or Periods) of Measure	Number of Index Components	Comments*
Adelman and Morris (1971)	73 74	— —	1963–1968 1957–1962	3 3	LDCs only
Author's Index (POLDEM)	123 113	0.88 0.89	1965 1960	6 6	See text for details
Coleman (1960)	66	—	1960 (?)	1	LDCs only, 3-rank scale
Coulter (1975)	85	—	1950–1970	3	Cutright (1963) as part of index
Cutright (1963)	77	—	1940–1960	2	African nations excluded
Cutright and Wiley (1969)	40	—	1927–1936 1937–1946 1947–1956 1957–1967	3 3 3 3	Similar to Cutright (1963) with addition of franchise measure
Jackman (1973)	60	—	1960	4	Communist countries excluded
Johnson (1977) Fitzgibbon-Johnson *Revised* Index	20	—	1945, 1950, 1955, 1960, 1965, 1970, 1975	5	Latin American countries only, excellent over-time coverage
Neubauer (1967)	23	—	1940–1960 (?)	4	Select sample of democratic nations, mostly MDCs
Smith (1969)	110	—	1946–1965	2	Cutright (1963) measure for one component, 20 assorted indicators for second component

* A number of these indices use indicators of stability and other measures of questionable validity. The comments in this table do not address this issue. See the text for discussion.

only index that approaches POLDEM in sample coverage. Jackman's (1973) and Cutright's (1963) indices have only 60 and 77 countries, respectively.

A number of these measures are limited to certain types of countries. For instance, Adelman and Morris (1971) and Coleman (1960) consider only LDCs. The Fitzgibbon-Johnson Revised Index is only for Latin American countries. Neubauer (1967) develops his measure for only relatively democratic nations (mostly MDCs). If the researcher wishes to restrict his/her attention to countries of a particular type (e.g., LDCs), then one or more of these indices may be suitable. But if the generality of hypotheses or the comparison of countries in different regions or at different levels of development is sought, then these indices will not do.

The third column of Table 3 lists the reliability of the indices. Unfortunately, none of the indices except POLDEM reports an estimate of reliability, so it is not possible to compare, directly, these measures. However, the indirect evidence that exists suggests that POLDEM compares very favorably with these indices.[15]

The temporal coverage of the indices of political democracy is also an important consideration. Table 3 shows that the Fitzgibbon-Johnson Revised Index covers the most time points. It is available for seven points of time over a 30-year period (1945–1975). The primary drawback is that the index is limited to Latin American countries. Adelman and Morris's (1971) measure is available for two five-year periods of time (1957–1962 and 1963–1968) but it is available for LDCs only.

Cutright and Wiley's (1969:27) measure extends the furthest back in time. The measure is available for four ten-year periods from 1927–1967. However, the sample is restricted to 40 nations that were self-governing and that continued to be self-governing during the full 40-year period. This criteria leads to the exclusion of many African and Asian nations from their sample.

The only index in Table 3 that is available for more than one time period, and is not restricted to only LDCs or Latin American countries (or some other group), is POLDEM. POLDEM is available for a diverse sample of countries in 1965 and 1960.[16] Although this is a short interval, an examination of the index values in Appendix 2 shows that some change did occur in a number of countries.

In summary, a comparison of POLDEM with nine other measures shows that it is the only index that reports an estimate of reliability. Given the magnitude of the coefficient and the number of components in the index, it is at least as reliable as the other measures. In addition, POLDEM is available for a greater number of (and a more heterogeneous sample of) countries than are the others. Two of the measures are available for more time points (or periods) than POLDEM, but these indices are limited in sample coverage.

Although these preceding considerations are important in empirical analyses, the overriding criterion must be the validity of the index. Earlier in the discussion, I questioned the validity of several indicators (e.g., political stability) used in other measures of political democracy. The six components of POLDEM were chosen to measure popular sovereignty (as reflected in electoral processes) and political liberties. The indicators appeared to have "face" validity. Yet, face validity is only a first step in the validation process.

The moderate-to-high intercorrelations between the components provide support for the internal validity of the index. But an internal check on validity is not a complete substitute for external checks. One method used to evaluate the external validity of this measure is correlating the scale with other indices that are intended to measure political democracy. The limitations of some aspects of these other measures were pointed out in an earlier part of this article. However, the index devised here would be suspect if it did not have positive and significant correlations with most of these previous measures. Table 4 presents the correlations of POLDEM with a number of previous indices appearing in the literature.[17]

---

[15] Two factors that affect the reliability of an index are the number of components and the average correlation of the components in the index. The next to the last column of Table 3 shows that POLDEM has more components than the other measures. The intercorrelation of components is not reported for many of these indices. An exception is Coulter (1975). The average correlation of his three components is less than 0.4, considerably less than the 0.7 average correlation of the components in POLDEM.

[16] Five of the six indicators used in this democracy index are also available for 1950 and 1955, so that the democracy measure could be constructed for an even-longer time period. However, the sample size available for these earlier years is much less than for the more recent time points.

Table 4. Pearson Correlations of POLDEM with Other Political Democracy Measures

Political Democracy Index	Correlation With Author's Political Democracy Index*	Number of Cases
Adelman and Morris (1971)		
1963–1968	0.68**	70
1957–1962	0.69	65
Coleman (1960)	0.69	52
Coulter (1975)	0.74	82
Cutright (1963)	0.76	73
Cutright and Wiley (1969)	0.85	40
Jackman (1973)	0.79	55
Johnson (1976) 1965	0.90**	20
1960	0.89	20
Lipset (1963)		
European	0.63	28
So. American	0.58	20
Neubauer (1967)	0.46	23
Smith (1969)	0.79	104

* All correlations are with the 1960 political democracy index (POLDEM) except those marked ** which are with the 1965 measure. All correlations are significant at the 0.01 level or better.

The magnitude of these correlations lends further support to the validity of POLDEM.[18] The lowest correlation (0.46) with Neubauer's (1967) democracy[19] is still a moderate relationship. The relationship between the Political Democracy Index (POLDEM) and the democracy measures devised for only LDCs is of particular interest since the greatest measuring inaccuracies are likely for developing countries. Table 4 shows that POLDEM correlates at about 0.7 with Adelman and Morris's 1963–1968 and 1957–1962 measures for developing countries. Considering the political change occurring during this period, and the fact that their measure is aggregated over a five-year period, this is a relatively strong relationship. POLDEM also correlates about 0.7 with Coleman's three-rank scale for LDCs and about 0.6 with Lipset's simple dichotomy measure for South American countries.

The highest correlations in Table 4 are between POLDEM and the Fitzgibbon-Johnson Revised Indices for 1965 and 1960. The correlation for both time points is about 0.9. The Fitzgibbon-Johnson index is only for Latin American countries. This specialization in Latin America, combined with its long history (since 1945), suggests that it is one of the best available measures for a region of developing countries. The high correlation of POLDEM with this measure further supports the use of the POLDEM for the analysis of LDCs.[20] POLDEM also correlates highly (0.74 or more) with the indices of Coulter, Cutright, Cutright and Wiley, Jackman, and Smith.

---

[17] A correlation matrix for POLDEM, Jackman's (1973), and Cutright's (1963) measures was also computed. For the 47 countries with data on all three measures, POLDEM correlated 0.81 with Cutright's index and 0.79 with Jackman's, while Cutright's measure correlated 0.61 with Jackman's.

[18] Considering the previously discussed limitations of certain indicators of the other indices and the fact that they are not all for the same time period, the magnitude of these correlations is impressive. Part of the reason for this is that at least some parts of the other indices are similar (and, in one case, the same) as are one or two of the components used in the revised index. For example, Cutright's (1963) index uses whether or not the chief executive is elected as part of his political development index. This is similar to one of the components used in the Political Democracy Index. Similarly, both the Political Democracy Index and Jackman's measure use the electoral irregularity variable.

[19] Part of the reason for the moderate correlation of Neubauer's measure with POLDEM is a result of the unusual indicators selected for his index (e.g., "information equality," as measured by the relative number and circulation of newspapers in capital cities; and "competition," as measured by the percentage of the time period in which the dominant party held office (1967:1005). This index does not seem to be for a single time *point* only but, rather, for a longer time *period*, so stability factors may be built into it. For an extensive critique of Neubauer's index, see May (1973). Additional criticism may be found in Cutright (1968). Also, the countries selected by Neubauer were all relatively democratic, restricting the variability of POLDEM. This may have led to a lower correlation than would be found if Neubauer had also included relatively nondemocratic countries in this sample. For a discussion of how the magnitude of the correlation coefficient depends on the range of variability in both variables, see Blalock (1972:381–3).

[20] Wendy Bhattacharyas (forthcoming) has also devised an index of political democracy for devel-

Given the magnitude of the relationships, one is tempted to conclude that it does not matter which measure is used because they are so closely related.[21] This argument suggests that the validity issues raised by other researchers, and here, are not important empirically. Such a view is suggested by Rubinson and Quinlan (1977:614). They state that, for all practical purposes, Jackman's and Cutright's measures are empirically indistinguishable: "... Jackman and Cutright indexes are so empirically interrelated that the difference between them is not sufficient to account for the different empirical results in their studies." (p. 614). This view conflicts with Jackman (1975:86–7), who claims that the incorporation of political stability into Cutright's (1963; 1967) measure has led to a spurious relationship between political democracy and social equality.

Since there is no agreement on whether the various democracy measures are empirically interchangeable, it is worthwhile to pursue this issue here. Several points are worth mentioning. First, the moderately high correlation between these measures can be overemphasized. For example, the correlation of 0.76 between POLDEM and Cutright's (1963) measure still means that over 40% of the variance of each measure is unexplained by the other. Although a part of this 40% may be explained by random measurement error, there is still a considerable fraction that could be accounted for by more systematic influences (e.g., Cutright's measure incorporating political instability in its construction).

A second factor to consider is that an association between variables does not necessarily mean that they are measuring the same concept. Two variables may also have a high correlation because part (or all) of one variable is causally related to the other. Or both variables may be spuriously related to some third set of factors. Since many of the politically democratic countries are also stable, the incorporation of stability into Cutright's (1963) measure of democracy does not necessarily mean that his measure will correlate low with other measures of democracy (e.g., Jackman's [1973] measure). But these arguments are still abstract and do not tell whether, *empirically*, the incorporation of stability distinguishes one index from another.

One empirical test is as follows.[22] If Jackman's (1973) index (JACDEM) and Cutright's (1963) index (CUTDEM) are both measuring the same concept of political democracy, then they should be empirically indistinguishable. If these indices are empirically indistinguishable, then most of the systematic variance in each index should be accounted for by the other index. In this case, the regression of one index on the other index and on some other variables should result only in a significant coefficient for the democracy index and not for any other variables in the regression.

Jackman (1975) and others have argued that Cutright's (1963) index (CUTDEM) is misleading because of its heavy reliance on political stability in its construction. If this argument is correct, then the regression of CUTDEM on JACDEM and a measure of political stability (POLSTAB) should result in a significant coefficient for

---

oping countries. The measure is for two time periods, 1959–1962 and 1963–1966. The first correlated 0.88 with the 1960 POLDEM and the second correlated 0.89 with the 1965 POLDEM.

[21] Of course, the sample and time coverage of some of the indices may lead to choosing one over another.

[22] The possibility of testing these validity arguments within a LISREL model was considered, but was decided against for several reasons. First, LISREL is a Full Information Maximum Likelihood (FIML) technique which is particularly sensitive to specification errors. Since this technique uses the information contained in all the equations in the model, a misspecification in one part has its effects spread throughout the model. Given the rather limited specification in the arguments presented here, a FIML technique may not be justified. A second, practical, consideration is that the components used in the other indices are not readily available. Third, even if the indicators for each index were available, there is a missing data problem which would severely reduce the sample size if all indicators were considered simultaneously. Such a small sample may not provide accurate estimates of relationships. Finally, the technique that is used has the advantage of being relatively simple and clearly demonstrates the effects of combining stability with political democracy.

POLSTAB even when JACDEM is controlled. On the other hand, if Rubinson and Quinlan (1977) are correct, once JACDEM is controlled, POLSTAB should not have a significant effect on CUTDEM.

The number of years, up to 1970, that the present constitutional form of a government has been in effect is used as a measure of political stability (Taylor and Hudson, 1971). The natural log of this variable is used to reduce skewness. This variable is referred to as POLSTAB. The regression of CUTDEM on JACDEM and POLSTAB results in:

$$\begin{aligned} \text{CUTDEM} = {} & 32.3 \\ & (3.64) \\ & + 0.211\ \text{JACDEM} \\ & \quad (0.057) \\ & + 2.23\ \text{POLSTAB} \\ & \quad (0.739) \end{aligned} \tag{2}$$

$$(\text{Standard Errors})\ R^2 = 0.48 \quad N = 48$$

Both JACDEM *and* POLSTAB are significant at greater than the 0.0001 level.[23] This means that—even controlling for the level of democracy as measured by Jackman—political stability has a significant association (not necessarily causation) with Cutright's index.

This difference in indices is further illustrated by regressing JACDEM on CUTDEM and POLSTAB. If JACDEM does not confound stability in its construction, then POLSTAB should not have a significant relationship once CUTDEM is controlled. The following regression tests this hypothesis:

$$\begin{aligned} \text{JACDEM} = {} & 2.85 \\ & (13.8) \\ & + 1.10\ \text{CUTDEM} \\ & \quad (0.298) \\ & + 1.97\ \text{POLSTAB} \\ & \quad (1.83) \end{aligned} \tag{3}$$

$$(\text{Standard Errors})\ R^2 = 0.39 \quad N = 48$$

In Equation (3) POLSTAB does not have a significant positive association as was found in Equation (2). This provides strong evidence that political stability is confounded with political democracy in Cutright's index.

Further evidence that stability has an empirically discernible effect on Cutright's measure is found when the Political Democracy Index (POLDEM for 1960) is substituted for JACDEM:

$$\begin{aligned} \text{CUTDEM} = {} & 32.9 \\ & (1.90) \\ & + 0.188\ \text{POLDEM} \\ & \quad (0.024) \\ & + 1.90\ \text{POLSTAB} \\ & \quad (0.622) \end{aligned} \tag{4}$$

$$R^2 = 0.63 \quad N = 73$$

$$\begin{aligned} \text{POLDEM} = {} & -65.0 \\ & (13.7) \\ & + 2.45\ \text{CUTDEM} \\ & \quad (0.317) \\ & + 1.77\ \text{POLSTAB} \\ & \quad (2.38) \end{aligned} \tag{5}$$

$$R^2 = 0.58 \quad N = 73$$

Once again controlling for democracy as measured by POLDEM, POLSTAB still has a significant positive association with CUTDEM. But POLSTAB does not have a significant association with POLDEM once CUTDEM is controlled.

The incorporation of stability in Cutright's measure can have consequences for theory testing. If a hypothesized cause of political democracy is related to political stability, but not to democracy, the use of a measure that confounds stability with democracy may result in a spurious significant relationship. To illustrate, consider the hypothesized relationship between the time of development and political democracy. De Schweinitz (1964), Moore (1966), and a number of other social scientists have hypothesized that the historical conditions conducive to democracy have steadily declined, over time. Thus, the early developers are more likely to be democratic than are the late developers. Those countries that have been developing the longest are generally the most stable. Therefore, a measure of "democracy" that also measures stability increases the likelihood of a positive relationship because of the relationship between stability and the number of years a country has been developing (Bollen, 1979).

To demonstrate this problem, three re-

[23] Significance is determined with a two-tail t-test.

Table 5. Regression of Author's, Jackman's, and Cutright's Measures of Political Democracy on Timing of Development and Level of Development

Independent Variable	Author's (POLDEM)	Jackman (1973) (JACDEM)	Cutright (1963) (CUTDEM)
	Dependent Variable		
Timing of Development	0.026 (0.054)[a]	−0.054 (0.048)	0.053* (0.021)
Level of Development (In energy cons. per capita, 1965)	10.20* (1.93)	9.74* (2.03)	2.97* (0.870)
R^2	0.44	0.37	0.54
N	99	57	60

[a] (standard error).

* Significant at 0.01 level.

gressions are run. The independent variables in each are the same: "l" in energy consumption per capita, 1965, as a measure of economic development; and Black's timing of development (Taylor and Hudson, 1971). The dependent variables are Jackman (JACDEM), Cutright (CUTDEM), and POLDEM. If the use of stability in Cutright's (1963) measure has no empirical consequences, the results of the regression should be similar to that using the two other measures. However, if the use of stability does lead to a spurious effect, then it is possible for the timing of development to have a significant relationship with Cutright's measure, but not with the other two. The results of these regressions are reported in Table 5.

Table 5 indicates that both the author's and Jackman's (1973) measures have *no* significant relationship with the timing of development, once the level of development is controlled. But Cutright's (1963) measure leads to a positive and significant relationship with development timing. This supports the hypothesis that the incorporation of stability in Cutright's measure can lead to spurious relationships with other variables that are related to stability, but not to democracy.[24]

More generally, these results conflict with Rubinson and Quinlan's (1977) claim that Cutright's (1963) and Jackman's (1973) measures are so closely related that the use of either will lead to empirically similar results. Rather, my analysis supports Jackman's claim that the incorporation of political stability in measures of political democracy may lead to spurious findings. This does not mean that differences in results always occur, but it does suggest that the selection of the indicators used in democracy measures has empirical consequences.

Discussion

Few concepts in the social sciences can be measured simply and directly. The concept of political democracy is no exception. As an abstract and complex concept, there are a large number of potential indicators that indirectly represent it. Yet each indicator is a fallible measure of political democracy.

In the ideal case, a random sample of all possible indicators of political democracy could be chosen, selecting a sufficient number to reach the desired reliability. Unfortunately, this is never the case. A number of desirable indicators of political democracy were not available; for example, the composition of the ruling elite and how representative they are of the general population, the extent of political discrimination, the mobility in-and-out of the political elite, the extent to which policy decisions are in accordance with the "will" of the people, and the real franchise (not the "legal" franchise) of the population.

In contrast to the need for *additional valid* indicators of political democracy, much of this article has argued against the indiscriminate use of other political indicators. Many of the conflicting results of empirical studies are likely to be a function of the indicators of political democracy used. For instance, Cutright's

---

[24] For a fuller discussion of development timing and political democracy, see Bollen (1979).

(1963; 1967) reliance on political stability in his index makes it difficult to determine whether political democracy or stability has an effect on income inequality. Other researchers have combined indicators of voter participation, socialist party strength, or party fractionalization—as well as stability—into indices of political democracy. I have argued that these concepts are important in their own right and should be kept out of indices of political democracy. Treating these concepts theoretically and operationally separate allows the researcher to determine if, for instance, a democratic political structure, high political participation, or some combination of high participation and democracy reduces inequality. Similarly, the impact of political stability on income inequality, independent of political democracy, can be determined *if* these concepts are measured separately and are *not* combined into a single index.

The index of political democracy presented here is designed to measure popular sovereignty (as represented in electoral processes) and political liberties. It does not consider political stability, voter turnout, socialist party strength, or labor union strength in its construction. Appendix 2 lists the index values for 1965 and 1960.[25]

It must be remembered that these are observed scores and not true scores. Small differences between countries on the index do not necessarily mean that the actual level of political democracy differs. For example, in 1965 Sudan scores 37.9 and Togo scores 45.5. This does not mean that the *true* political democracy score of Togo is greater than Sudan. Due to measurement error, each true score gives rise to a number of different observed scores. So it is possible that Sudan and Togo have the same true score even though their observed scores differ. Of course, the greater the distance between observed scores, the more likely two countries' true scores differ. But for smaller differences the researcher should not overinterpret these or any other values.

The validity of the political democracy index was explored in several ways. First, the face validity of each component was discussed. Only those measures that corresponded to the theoretical definition of political democracy were selected. Second, the relatively high intercorrelation of the indicators provided some evidence of the internal validity of the indicators. Furthermore, a confirmatory factor analysis supported the hypothesis that the assumed latent political democracy variable has a significant effect on all six components. Finally, the moderate-to-high correlation of the index with other proposed measures of political democracy provided support for its external validity. Further discussion and tests of the validity of this index are desirable. Perhaps the ultimate validity test is the utility of the index in cross-national research.

APPENDIX 1

Confirmatory Factor Analysis of the Six Indicators of Political Democracy

The six components of POLDEM are assumed to be caused by a single latent variable (i.e., political democracy) and random errors of measurement. This structure is represented in Equation (A1):

$$\begin{bmatrix} Y_1 \\ Y_2 \\ Y_3 \\ Y_4 \\ Y_5 \\ Y_6 \end{bmatrix} = \begin{bmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \\ \lambda_4 \\ \lambda_5 \\ \lambda_6 \end{bmatrix} \eta + \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \\ \epsilon_3 \\ \epsilon_4 \\ \epsilon_5 \\ \epsilon_6 \end{bmatrix} \quad (A1)$$

In Equation (A1) Y_1 through Y_6 represent the six indicators of political democracy as defined in Table 1 of the text. The Y_i's are assumed to have a multivariate normal distribution.[26] The unmeasured political democracy variable is represented by η.

Measurement errors in the variables are represented by ϵ_1 to ϵ_6. These errors of measurement are assumed, independent of η. All variables are measured as deviations from their means and it is assumed that the E (E_i) is zero.

Figure A1 is a path diagram of this structure.

---

[25] The index values are listed according to the Russett et al.'s (1968) Standard Country Code, to facilitate the merger of the data with any others of a number of cross-national data sets (e.g., Taylor and Hudson, 1971) that also use this country code.

[26] The assumption of a multivariate normal distribution is probably not met by this data. Part of the reason for this is the relatively few values that some of the indicators take. The robustness of the model to the violation of this assumption is not well understood. Stapleton (1977:62) suggests that LISREL estimates still have merit even when this assumption is violated. However, further research is needed:

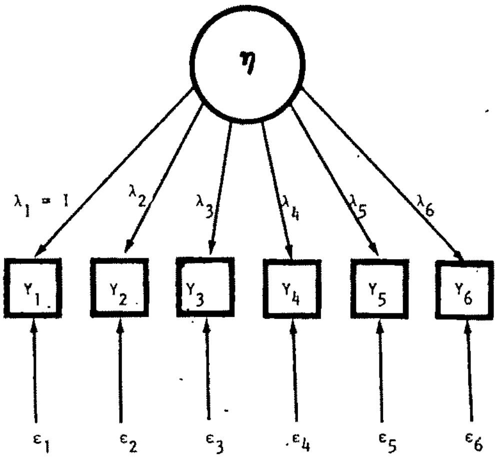

Figure A1. Initial Specification of Political Democracy (η), Determining Six Components ($Y_1 - Y_6$)

The λ_i's summarize the expected change in the Y_i's for a one-unit change in political democracy (η). A one-unit change in η, for instance, is expected to change Y_2 by λ_2. The scale for measuring η is arbitrary, but should be fixed to estimate the model. To resolve this indeterminacy of scale, λ_1 is set equal to 1. This sets the scale of η to Y_1 and allows estimation of the model (Sörbom, 1975:140). For this initial specification, the errors of measurement are assumed to be independent ($E(\epsilon_i\epsilon_j) = 0$ for $i \neq j$).

The model represented in Figure A1 is estimated using the covariance matrix[27] of the six indicators for 1960. A χ^2 value is calculated to evaluate the fit of the model. The probability level (P) of the χ^2 is "the probability of getting a χ^2 value larger than the value actually obtained, given that the hypothesized pattern is true. Thus, small values of P correspond to poor fit and large values to good fit" (Jöreskog, 1969:195).

The χ^2 (9 degrees of freedom) of the structure in Figure A1 is 38.92 with P less than 0.0001. Although all the estimated λ_i's are highly significant, the overall fit is not good. The poor fit of this initial estimate is probably a result of improper restrictions in the hypothesized structure. By relaxing some of these restrictions, improvement in fit may result. There are several empirical techniques for selecting which restrictions to relax (see Sörbom, 1975; Long, 1976), but as Saris et al. (1978:157) state: "Corrections of the model on theoretical grounds would generally be preferred. . . ."

Reconsidering the model diagrammed in Figure A1, the most questionable assumption is probably that of the independence of the errors of measurements. This means that any error of measuring legislative selection (ϵ_6), for instance, is not related to the measurement error of executive selection (ϵ_5), or the measurement errors of any of the other variables. This may not be realistic. Since freedom of group opposition (Y_2), executive selection (Y_5), and legislative selection (Y_6) are all constructed by the same source (Banks, 1971), the errors of measurement may be correlated. The use of freedom of group opposition (Y_2) and freedom of the press (Y_1) in forming the government sanction variable (Y_3) suggests that the measurement error of the last variable (ϵ_3) should be freed to estimate its possible correlation with ϵ_1 and ϵ_2. This revised structure is represented in Figure A2.

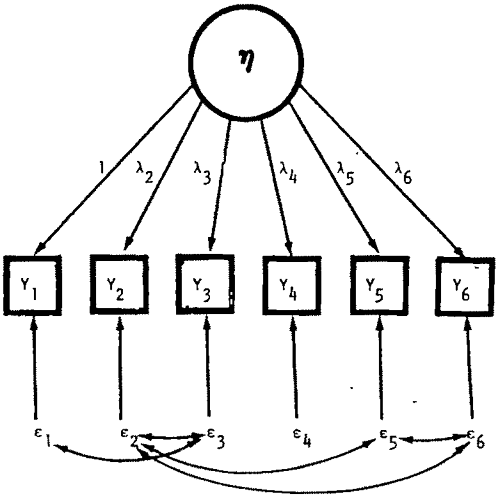

Figure A2. Political Democracy (η) Determining Six Components ($Y_1 - Y_6$), Allowing Certain Correlated Measurement Errors

Estimation of this model results in a χ^2 (4 d.f.) of 4.62 with a probability of 0.3282. The total fit is good but an important question is whether its fit is better than of the model of Figure A1. The difference in χ^2 values and degrees of freedom of Figure A1 and Figure A2 forms a new χ^2 value that addresses this question. If the difference in χ^2 values is not significant, then the fit of the more restricted model with uncorrelated measurement errors (Figure A1) is not significantly different than the more general model of Figure A2. On the other hand, a significant χ^2 suggests that the restricted model of Figure A1 does not have as good a total fit as does Figure A2. In this case a χ^2 difference (5 d.f.) of 34.3 results. This is highly significant ($p < 0.001$), so the hypothesis of no significant difference in fit is rejected, indicating that Figure A2's fit is better than that of Figure A1.

Although the *total* fit of Figure A2 is good, the estimated covariances, $\hat{\sigma}_{\epsilon_1\epsilon_3}$ and $\hat{\sigma}_{\epsilon_2\epsilon_5}$ are not statistically significant at the 0.05 level. Therefore, the model is reestimated setting these covariances to zero. Figure A3 presents the resulting model.

---

[27] The lower half of the symmetric covariance matrix of Y_1 to Y_6 for 1960 is: 100.5, 104.2, 182.2, 45.4, 66.7, 33.1, 80.2, 90.4, 40.6, 106.5, 86.7, 103.3, 48.2, 84.4, 197.7, 86.7, 121.3, 49.3, 81.1, 108.2 and 127.7.

The χ^2 (6 d.f.) is 5.57 with a probability of 0.4731. In addition, all the estimated parameters are significant at the 0.05 level.

Figure A3 represents a more restricted model than Figure A2. The difference in χ^2 values of these two models helps determine whether the restricted model of Figure A3 has a significantly worse fit than the more general model of Figure A2. The difference of χ^2's (2 d.f.) is only 0.95, which is not even significant at the 0.95 level. Therefore, the model of Figure A3 is chosen over Figure A2.

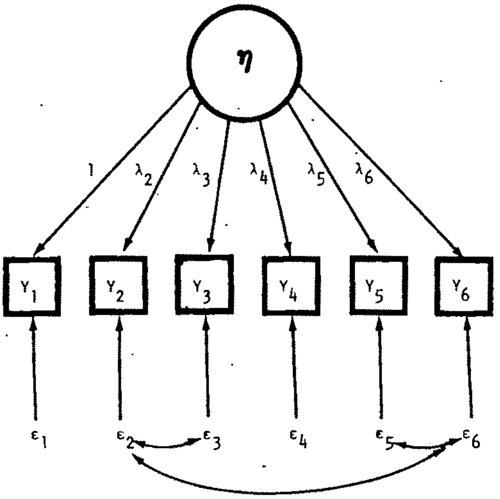

Figure A3. Political Democracy (η) Determining Six Components ($Y_1 - Y_6$) Reestimated, Setting Nonsignificant Covariances of Measurement Errors to Zero

One final restriction is tested. The estimates of λ_5 and λ_6 appear equal to λ_1 which is constrained to one. To test this additional restriction, the model is reestimated with the constraint that $\lambda_1 = \lambda_5 = \lambda_6 = 1$. Figure 1 in the text reports these final estimates. The χ^2 (8 d.f.) is 5.78 with a probability of 0.6716. The difference in χ^2 values (2 d.f.) of Figure 1 and Figure A3 is only 0.21 ($p > 0.99$). Thus, these two additional constraints lead to a model with two additional degrees of freedom, and a fit not significantly different from that of Figure A3.

Table A1 presents a summary of the χ^2 fit of the models discussed in the Appendix. Table A2 summarizes the comparisons of fit.

Table A1. Summary of Models in Confirmatory Factor Analysis of 1960 Indicators of Political Democracy

Model	χ^2	d.f.	Probability Level
Figure A1	38.92	9	0.000
Figure A2	4.62	4	0.328
Figure A3	5.57	6	0.473
Figure 1	5.78	8	0.672

Table A2. Comparison of Models in Confirmatory Factor Analysis of 1960 Indicators of Political Democracy

Model (Restricted vs. General)	Difference of χ^2	d.f.	Probability Level
Figure A1 vs. A2	34.3	5	Less than 0.001
Figure A3 vs. A2	0.95	2	Greater than 0.950
Figure 1 vs. A3	0.21	2	Greater than 0.990

ORGANIZATIONAL PROPERTIES FROM AGGREGATE DATA: SEPARATING INDIVIDUAL AND STRUCTURAL EFFECTS*

JAMES R. LINCOLN

GERALD ZEITZ
SUNY, Stony Brook

American Sociological Review 1980, Vol. 45 (June:391–408)

In this paper, we argue that aggregate measures (means computed on distributions of individual scores) may be valid indicators of organizational properties which also enable an investigator to determine whether statistical relations among organizational measures arise from organization-level, as opposed to individual-level, causal processes. We review certain statistical aggregation issues as these pertain to organizational analysis, and we propose Hauser's path analytic model of analysis of covariance as a device for separating individual and structural effects. These methods are then applied to data gathered in a survey of 20 social service organizations. We specify and estimate a causal model wherein administrative intensity, lateral communications, and decentralization of decision making are endogenous variables. We find that a number of "total" effects on these properties mask quite different—and in some cases contradictory—processes at individual and organization levels. Among other inferences, we suggest that the organizational- and individual-level influences we observe on decentralization raise questions regarding certain widely accepted interpretations of this property. We recommend that analysts working with aggregate measures adopt similar procedures in order to fully exploit their data for the insights that may be gained into multilevel organizational processes.

Introduction

This paper combines a study of decision-making decentralization in social service organizations with a discussion of issues and opportunities posed by aggregating data on organizational members to produce measures of organizational structure. We think that aggregate measures can be valid indicators of organizational properties. And, unlike "global" measures, they permit dissection of observed relations between organizational traits into components attributable to organizational- and individual-level causal processes. Some background to our discussion may be found in the attempts to treat "structural" effects in organizational analysis by Blau (1957; 1960), Coleman (1959), and Tannenbaum and Bachman (1964). Yet their observations have had little sustained impact on organizational research; primarily, we think, because the methodology for separating individual and structural effects was at the time poorly understood (Hauser, 1970). The state of the art has advanced since then, however, and methods of partitioning aggregate variable relations into their organizational and individual components are today readily available. We use such methods in the present investigation to show that tests of structural theories could benefit from the insights these methods permit into the causal processes at multiple levels which generate patterns in organizational data.

These issues are of some general relevance, for a significant body of research on organizational structure has been built on findings obtained with aggregate data (Aiken and Hage, 1966; R. B. Duncan, 1972; Glisson, 1978; Hage and Aiken, 1967; Hall, 1963; Lawrence and Lorsch, 1967; Pennings, 1975). Approaches to the measurement of organizational properties were for some time bifurcated into what Pennings (1973) has called "subjective" and "objective" methods. The subjective method meant the collection of responses from individual members of organizations which, upon aggregation, yielded measures of structural properties for the organ-

A previous version of this paper was presented at the 74th annual meeting of the American Sociological Association in Boston, August, 1979. We are indebted to Duane F. Alwin, Larry J. Griffin, David Knoke, and Maurice Garnier for helpful comments on a previous draft. They are in no way responsible for deficiencies that remain, however.

ization as a whole. Objective strategists performed content analyses of formal documents and key informant interviews to produce "global" measures—that is, those not reducible to individual traits (Lazarsfeld and Menzel, 1961).

While Pennings's (1973) concern lay with the convergent validity of these modes of organizational measurement, that is not our interest here. However, in the debate surrounding these methods, certain views were aired which are pertinent to the problems we address. Several critics of the subjective methodology expressed doubt that the averaged perceptions or traits of organizational participants could be meaningfully identified with structural properties of the organization (Hinings and Lee, 1971; Pennings, 1973; Tausky, 1967). We agree that some aggregate measures may indeed be of doubtful validity. But the same is true of global measures, and the validity issue does not turn on this distinction. It would be hard to improve upon the proportion of administrators in an organization as an indicator of administrative intensity. Yet this is an aggregate measure in our sense: the mean of the membership's distribution on a binary variable measuring occupancy or nonoccupancy of administrative positions.

Several writers have also alluded to problems of interpretation engendered by aggregation (Aiken and Hage, 1966; Pennings, 1973; Tannenbaum and Bachman, 1964). By computing correlations among averages of individual traits, can one be sure that the observed statistical relationships derive from organizational-, as opposed to individual-level, processes? For example, if the proportions of professionals and members who report participating in decisions are correlated over organizations, perhaps the only process at work is that of individual professionals influencing decisions more frequently than nonprofessionals. This being the case, one might hesitate to claim support for a more complex "structural" theory relating professionalization as an organizational attribute to decentralized decision making (Blau, 1968; Hall, 1968).

We think this is a legitimate concern. It frequently is relevant to the aims of research to know whether an empirical relation between organizational properties stems from an organizational or an individual process. But the fallacy here lies in assuming that such interpretive ambiguity occurs only when organizational properties are estimated using averaged members' traits or perceptions. In fact, these same questions concerning the locus of causation may legitimately be raised when organizational properties are measured with global indicators not derived from, nor disaggregable to, individual characteristics. In the case of aggregate measures, the analogous indicator at the individual level is readily apparent since its distribution is the raw material from which the organizational measure is derived. But the fact that a global measure does not have an immediately evident or accessible microcounterpart does not make it immune to questions concerning the level at which one's theoretical explanations should be pitched.

We see three dimensions to the level of analysis problem. These pertain to: (a) operational measures; (b) theoretical variables; and (c) relations between theoretical variables. Lazarsfeld and Menzel (1961) restricted their discussion to the measurement level and observed that "analytical" (aggregate) and global measures may be made of the same underlying property. It is clear, however, that not all individual attributes may be averaged to produce a theoretically meaningful organizational property; nor may all organizational properties have meaningful analogues for individuals. Job satisfaction, for example, is an individual sentiment only, and we think no purpose is served by aggregating satisfaction scores to produce an organizational mean (Aiken and Hage, 1966; Talacchi, 1960). Size and division of labor, on the other hand, are organizational properties which have no parallels as individual traits. The division of labor may, of course, express itself at the individual level in the range of skills or responsibilities involved in tasks. But the average breadth of work roles in the organization and its division of labor—the variety of work roles—are hardly equivalent concepts (but cf. Hall, 1963).[1] This example does serve, however, to illustrate the third dimension: the level at which a causal relation occurs. Division of labor might be thought to centralize decision making through an individual-level process. Differentiation of functions could narrow the scope of individuals' tasks, implying greater routinization and less autonomy and opportunity to exercise discretion. Aggregated to the organization level, these effects produce a skewed (that is, centralized) decision-making distribution.

Thus, a reasonable theory may specify that the intervening process producing an observed relation between organizational properties is wholly an individual one (Blau, 1957). At the opposite extreme is the case where such an individual-level process is conceived solely as a source of measurement error, confounding one's ability to estimate true relations between organizational traits. If multiple informants are asked to report on the same objective state of the organization (for example, on how many levels there are in the authority hierarchy), we can assume that any individual-level effects of their background characteristics (age, rank, sex, education) represent measurement bias. Note that it is *not* correct to assume, as Seidler (1974) does, that organization-level covariations between informant background traits and the reported property are necessarily symptomatic of bias. In a perceptive comment on Seidler's paper, McGranahan (1976) notes that the composition of the organization on informant background variables may reflect meaningful organizational properties belonging in one's theoretical model: education could be an indicator of professionalization, for instance. But to the extent that the process relating education to reported levels in the hierarchy is an individual one (more highly educated persons reporting more or fewer levels), such effects would be viewed rightly as errors to be held constant in evaluating relations among organizational variables.

It is important to stress, however, that the measurement error interpretation can incontrovertibly be applied only to cases where within-organization variation in informant reports is illogical, substantively. The earlier-cited example meets this criterion. Assuming a single hierarchy, informant disagreement as to its number of levels indicates error. But take a less obvious example. Informants might be asked whether they perceive the environment to be stable or changing (R. B. Duncan, 1972). In this case, intraorganizational variation in reports might be real variability in the task environments experienced by participants in different organizational positions (Roberts et al., 1978). As Comstock and Scott (1977) point out, organizational theory predicts effects on structure of task and environmental variability at individual, subgroup, and organization levels. It is, thus, not always easy to tell whether the organizational property in question is subject to real variability at the microlevel. Therefore, the optimal approach to these issues, we believe, is to separate individual and organizational effects whenever the data permit. Since aggregate measures of organizational properties readily permit such decomposition while global measures do not, this dictum favors an expanded role for aggregate measurement in organizational research.

Some Aggregation Issues

Our methodology for decomposing a relation between aggregate organizational

---

[1] This example underscores the ambiguity of the term "aggregate" in our discussion. We follow dominant usage and intend by it means, proportions, and other averages computed on distributions of individual (or other subunit) scores. Such central tendency measures are subject to a smilar interpretation as that applied to individual observations as the "level" of some variable. The level of decision-making participation, for instance, could refer to whether the individual participates or the proportion of individuals participating. As Lazarsfeld and Menzel (1961) noted, however, measures of dispersion or inequality computed on such distributions have the status of "global" indicators, for they permit no counterpart interpretation at the individual level. Comstock and Scott (1977), for example, measure differentiation in organizations with the index of qualitative variation, Σp_i^2, where p_i is the proportion of persons in the ith organizational position and the summation is over all positions.

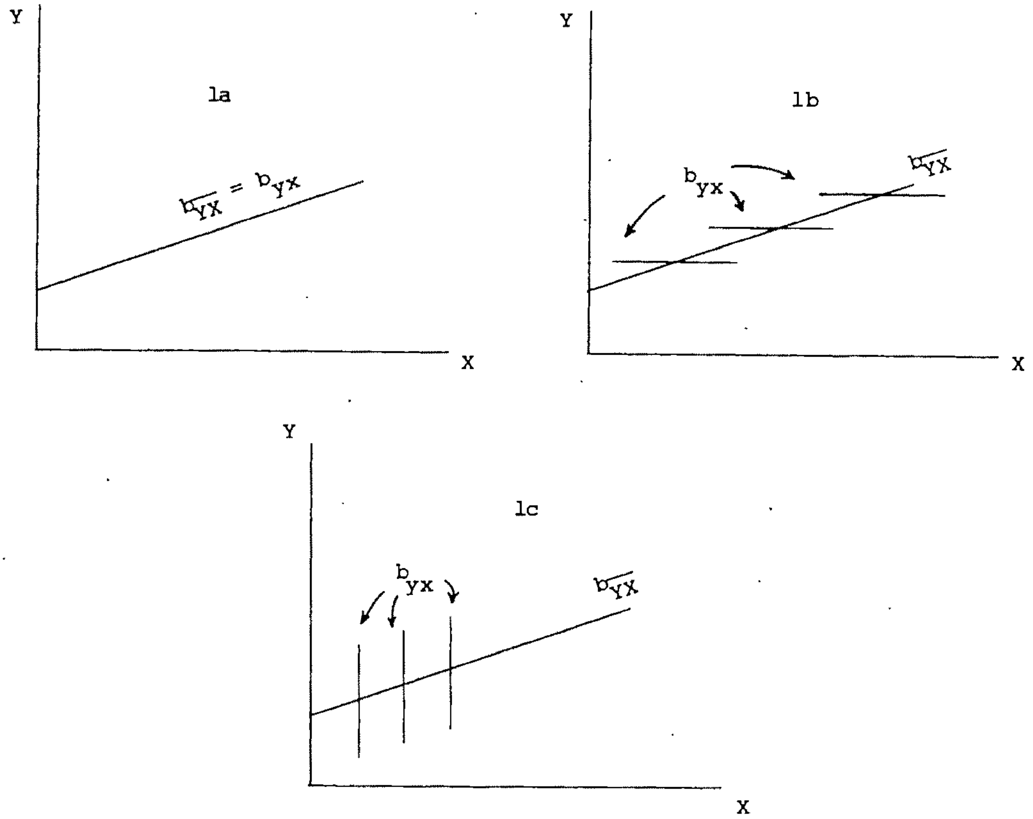

Figure 1. Examples of Possible Within- and Between-Organizations X, Y Relations

measures into its organizational and individual components rests on the established premise that aggregate variable relations can be shown to depend in certain ways on the relations between the disaggregated forms of the same variables (Hannan, 1971; Hauser, 1971:chap. 2). Let us illustrate. Figures 1a and 1b show that the same regression of organizational means, $b_{\bar{Y}\,\bar{X}}$, may arise in the presence of very different patterns involving variables X and Y within organizations. As we shall demonstrate, a proper interpretation of $b_{\bar{Y}\,\bar{X}}$ rests not only on its value and sign but also on a comparison between it and b_{yx}, the average within-organization slope.[2] An assumption required throughout is that the regression of Y on X within different organizations may be described by a common slope.

In Figure 1a, $b_{\bar{Y}\,\bar{X}} = b_{yx}$. If organizations selected or socialized members so that average levels of X varied between organizations, and a positive change in an individual's X produced a positive change in that person's Y, we would expect to observe this outcome. Thus, organizations might vary in the proportions of professionals they employ. Since professionals are powerful actors in organizational settings, average levels of influence should rise with professionalization. Note that the causal process relating professionalization to decentralization operates at the individual level. The only organizational "effect" is that which sorts members on X (professional status) by organization.

---

[2] $b_{\bar{Y}\bar{X}}$ and b_{yx} are the unstandardized coefficients from the regressions of $\bar{Y}_j$ on $\bar{X}_j$ and y_{ij} on x_{ij}, respectively. $\bar{Y}_j$ and $\bar{X}_j$ are the means of the jth organization on Y and X, while y_{ij} and x_{ij} are the deviations of individual members' scores from the means of their organizations. b_{yx} is an *average* within-groups (i.e., organizations) slope and may not describe the regression of y on x for any given j. We assume, however, that variation over j in the observed organization-specific slopes is within sampling error of b_{yx}. Tests for statistical interaction between organization and our independent variables upheld that assumption here.

Figure 1b illustrates a different state of affairs. Within an organization, to be a professional has no influence on one's decision-making involvement: the within slope, b_{yx}, is zero. Any regression of Y on X occurs through the organizational means. The implication here is that highly professionalized organizations distribute greater influence to professionals and nonprofessionals alike. Thus, professionalization is found to affect decentralization through a process which operates wholly at the organization level.

Suppose our interest lay not in the effect of professionalization but in that of size. Size, as we pointed out, is a global property which has no counterpart at the individual level. Thus, the regression of decision making on size could be plotted, as in Figure 1c. Since size is a constant for all individuals in the same organization, no within-organization regression may be contemplated, and the total regression is that relating means on Y to values of X. Similarly, Figure 1b would also describe the regression of a global measure—the Aston centralization scale, for example—where the data points are individuals (Pugh et al., 1968). Even though centralization might be thought to have an individual-level analogue (participation in decisions), the global measurement of this property means it is a constant for members of a common organization which may be associated only with average (mean) levels of professionalization.

Our concern is the converse of that addressed by a host of writers whose interest lies with aggregation bias in the use of group-level data to estimate variable relationships for individuals (Hannan and Burstein, 1974; Hammond, 1973; Burstein, 1978). As Firebaugh (1978) points out, the presence of such bias, which is measured by the difference in between- and within-group slopes, may testify to the existence of a causal process operating at the group level which is qualitatively different from that found at the individual level. If the goal is to generalize from aggregate observations to individuals, such group effects are a nuisance and confound cross-level inferences. But if the theory is couched at the group or organization level, evidence that the individual-level effects deviate from those observed for aggregates may be highly relevant to a test of it.

The group effects we allude to were first labeled "structural" effects by Blau (1960) but are more commonly called "contextual" effects (Hauser, 1970). Previous attempts to conceptualize and research contextual effects have in common a focus on how the group or organizational setting influences the attributes or behaviors of its individual members. Both the early applications of contextual analysis to organizational problems (Blau, 1960; Tannenbaum and Bachman, 1964), as well as the more sophisticated recent treatments of school effects on student attitudes and performance (Alexander and Eckland, 1975; Alwin and Otto, 1977; Hauser, 1971), take the individual to be the unit of analysis. This orientation is notably different from our concern with interpreting relationships among organizational properties which are measured with aggregate indicators. Consequently, while the methodology we employ is taken from the literature on contextual effects, our adaptation of it—to problems wherein the theoretical unit is the organization—calls for certain special manipulations which have no precedents in organizational research. We discuss the model underlying those manipulations, in the following section.

Contextual Analysis and the ANCOVA Model

A contextual effect traditionally has been presumed to exist if some individual level attribute, Y, displays a net association with the group mean on a predictor, $\bar{X}$, controlling for X, the individual's score on the predictor. Thus, one would wish to estimate the regression equation:

$$Y = a + b_{YX \cdot \bar{X}} + b_{Y\bar{X} \cdot X} + e \qquad (A)$$

As Alwin (1976; see also Werts and Linn, 1971)has shown $b_{YX \cdot \bar{X}} = b_{yx}$, the average within-group slope, and $b_{\bar{Y}\bar{X} \cdot X} = b_{\bar{Y}\bar{X}} - b_{yx}$, the difference in the between and within-group slopes.[3] The contextual effect is measured, then, by the degree to which the group-level slope deviates from the individual-level slope within groups. This difference, as the contrast between our Figures 1a and 1b makes plain, also measures the extent to which theorizing in terms of group or organization-level causal processes is warranted by the data.

---

[3] We do not reproduce Alwin's derivations but they depend merely upon multiplying through (A) by $\bar{X}_j$ and X_{ij} and solving for $b_{YX \cdot \bar{X}}$ and $b_{Y\bar{X} \cdot X}$.

Because it takes the individual as unit of analysis, however, the standard regression method of evaluating contextual effects permits a less clear interpretation of how an aggregate relation derives from group and individual-level processes than does an alternative (if formally equivalent) approach. Furthermore, the modelling strategy to which we now turn has the added advantage of permitting one to grasp directly the implications of introducing global variables with no intraorganizational variation, as well as additional aggregate variables.

Duncan et al. (1972:195) and Alwin (1976) discuss the model which concerns us, but their treatments are basically elaborations on a theme best developed by Hauser (1971:chap. 2). Hauser's model is a path analytic conceptualization of analysis of covariance. Given two interval-scaled variables, X_{ij} and Y_{ij}, where i indexes individuals and j indexes groups, the total regression of Y_{ij} on X_{ij} may be decomposed into the component causal processes displayed in Figure 2. Although Hauser's treatment is in terms of path coefficients, our purposes are better served by concentrating on unstandardized coefficients. Y_{ij} and X_{ij} are shown to be completely determined by the sums of their within (x_{ij}, y_{ij}) and between ($\bar{Y}_j$, $\bar{Y}_j$) components. x_{ij} is by definition independent of $\bar{X}_j$ as y_{ij} is independent of $\bar{Y}_j$. Part of the effect of X_{ij} on Y_{ij} is through the path relating x_{ij} to y_{ij}, the within-group regression. The other part is through the effect of $\bar{X}_j$ on $\bar{Y}_j$. But note that this effect may itself be decomposed into two paths, and it is this decomposition which concerns us chiefly here. One such path, measured by b_{yx}, the within-

groups slope, is mediated by a term denoted "C." C is the predicted value of $\overline{Y}_j$ from its constrained regression on $\overline{X}_j$; the constraint being that $b_{\overline{Y}\overline{X}} = b_{yx}$. The second path is mediated by "R," where $R = \overline{Y}_j - C$. Thus, R is the residual in $\overline{Y}_j$ from its constrained regression on $\overline{X}_j$. R is a normal byproduct of analysis of covariance: the group mean of Y adjusted for composition on X (Schuessler, 1969).

As Alwin (1976) notes, the effect of $\overline{X}_j$ on C is measured by b_{yx}, the within-groups slope. If $b_{yx} = b_{\overline{Y}\overline{X}}$, R would be the residual from the ordinary least-squares regression of $\overline{Y}_j$ on $\overline{X}_j$ and thus would be uncorrelated with $\overline{X}_j$. Any observed effect from $\overline{X}_j$ to R, therefore, must arise from a discrepancy between $b_{\overline{Y}\overline{X}}$ and b_{yx}, and, as Alwin (1976) shows again, to regress R on $\overline{X}_j$ is to produce a regression coefficient equal to $b_{\overline{Y}\overline{X}} - b_{yx}$. The model thus demonstrates that part of the effect of $\overline{X}_j$ on $\overline{Y}_j$ stems from the same individual-level process that connects x_{ij} and y_{ij} in the lower half of the model. Should there remain a residual effect of $\overline{X}_j$ on $\overline{Y}_j$, purged of this individual-level component, it implies the existence of a different causal process at the group level from that operating at the individual level.[4]

Although $b_{\overline{Y}\overline{X}} - b_{yx}$ and b_{yx} are the same estimates of group and individual effects, respectively, which would be obtained via Equation A, the ANCOVA model allows other insights into the processes at work which the conventional regression method obscures. One such insight is that the contextual effect, $b_{\overline{Y}\overline{X}} - b_{yx}$, describes a component of the relation between $\overline{Y}_j$ and $\overline{X}_j$; the aggregate or group-level relation. To refer to a contextual effect on individuals, which is the theme, as we pointed out, of most literature on this topic, is to consider an *indirect effect*, one which operates on individuals only through their membership in a common group (Hauser, 1971: Chap. 2).[5] Secondly, the model reveals the point at which a global variable such as size (S) would intervene. Such a variable could have no effect on the within-group component of the process relating X_{ij} to Y_{ij} as our Figure 1c showed. Its inclusion or exclusion from the model is therefore irrelevant to the estimate of b_{yx}. Moreover, since $\overline{Y}_j$ and C are wholly determined, any direct effect of size would be confined to R.[6]

An Empirical Application: Decentralization in Social Service Organizations

In the sections to follow, we apply the analyses described earlier to data gathered by a survey of social service agencies in a large midwestern metropolis.

---

[4] Cronbach (1976:3.18) has criticized the substantive interpretation of $b_{\overline{Y}\overline{X}} - b_{yx}$ as a contextual effect. In his view, only if the "selection factor[s]"—the variable(s) on which individuals are sorted into groups—are fully captured by the measured independent variables in the model would such an interpretation be warranted. If not, the model is misspecified, and $b_{\overline{Y}\overline{X}} - b_{yx}$ is a biased estimate of the contextual effect. While we take Cronbach's concerns seriously, we are not persuaded that the specification problem is any more serious here than with respect to models pitched at a single level of analysis. We have no a priori reason to assume that there exist unmeasured selection variables determining the distribution of persons among these organizations which are linearly related to the variables in our model.

[5] Because $b_{Y\overline{Y}} = b_{\overline{Y}R} \doteq 1.0$, the contextual effect is estimated with the same value $(b_{\overline{Y}\overline{X}} - b_{yx})$ regardless of whether Y, $\overline{Y}$, or R is taken as dependent variable. However, since $s_{\overline{Y}}/s_Y$ and $s_R/s_{\overline{Y}}$ normally will be less than 1.0, the standardized effect of $\overline{X}_j$ on Y_{ij} will be smaller than its similarly measured influences on $\overline{Y}$ and R (Hannan et al., 1976:139). It is, therefore, not surprising that school effects studies typically fail to find large path coefficients measuring the influences of contextual variables on student behavior and attitudes. To the degree that that Y variance lies within schools, rather than between them, standardized estimates of such effects will be reduced. If the research goal is to determine the influence of group (e.g., school) context *relative* to that of individual-level determinants, it may be reasonable to thus take the individual as unit of analysis (Alexander and Griffin, 1976). But if the goal (as in our case) is to ascertain whether and how some properties of collectivities affect others, then an individual-level analysis is inappropriate.

[6] In an otherwise trenchant critique of Bidwell and Kasarda's (1975) attempt to use aggregate student performance data to evaluate the organizational effectiveness of school districts, Hannan et al. (1976) state erroneously that the unstandardized coefficient (b_{IS}), which takes, say, student ability (I) as dependent upon some global property of the district (S), such as size, is subject to aggregation bias: a difference in the district-level and student-level slopes. This is incorrect. To regress an individual-level trait on a global trait yields the identical coefficient as the regression of the group mean of that variable on the same global property of the group.

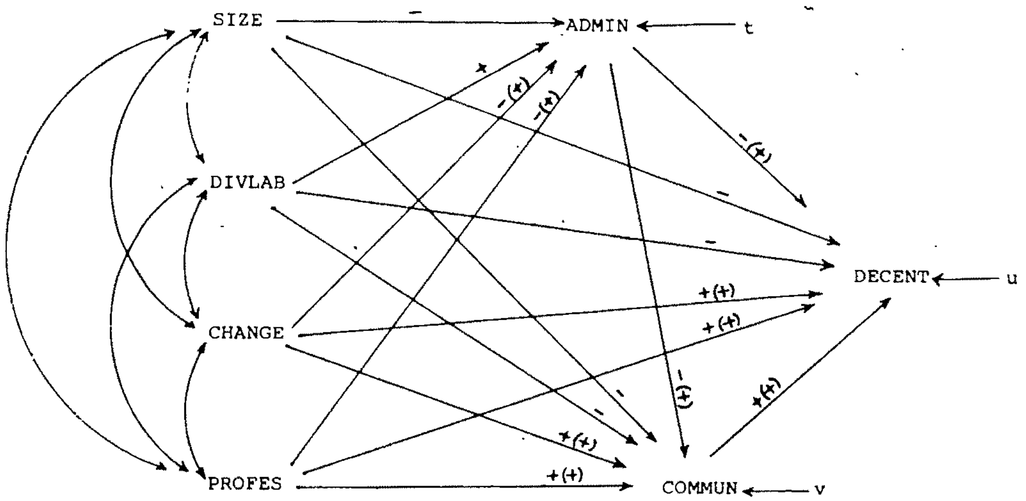

Figure 3. Causal Diagram of Processes Leading to Decision-Making Decentralization (Note: Signs indicate predicted direction of effect at the organization level and individual level (in parentheses).

A sample of 548 members of 20 public and private agencies responded to questionnaires or standardized interview schedules. The organizations ranged in size from 11 to 248. They were chosen randomly from a field of 85 human service agencies with staffs of ten or more, as listed in the Directory of Services published by the local welfare planning agency. The response rate varied from a low of 51% in one public welfare agency to 100%. The overall response rate was 71%.[7]

We will propose a simple model designed to explain decision-making decentralization in organizations. Figure 3 diagrams that model. The specific measures of variables we examine are discussed in an appendix. All such variables are means on distributions of scores derived from individual members with the exceptions of size (1n. total employees) and division of labor (no. occupational titles). Since any relation, in which both dependent and independent variables are means, may be partitioned into its organizational- and individual-level components, Figure 3 includes predicted signs of both micro- and macroeffects of all variables but size and division of labor. Our reasoning behind these predictions follows.

The size, division of labor, level of professionalization, and change in the task environment are specified as exogenous variables. Administrative intensity is taken as the first endogenous variable to be determined by these factors. We hypothesize, following Blau (1970), that administrative intensity is inversely dependent upon size (because of administrative economies of scale) and directly dependent upon division of labor (because of increased coordination problems). Following Burns and Stalker (1961), Hage (1965), and others, we predict that administrative intensity should fall with rising professionalization and task environment change. The argument here is that professionalism and instability or uncertainty are both forces rendering close supervision and high administrative overhead ill-suited to effective performance. We acknowledge, however, that some investigators have found empirical patterns which deviate from this prediction. Blau (1968), for example, found a higher proportion of administrators in organizations where the average level of employee expertise was high, although his initial hypothesis was the same as our own. We should note that herein lies a case where one would predict very different organization-level and individual-level processes at work. The theory we advanced, positing an inverse relation, is pitched at the organization level. At the individual level, we think it highly probable that professionals (in terms of expertise or orientation to professional reference groups) might also be administrators (in the sense of wielding supervisory power). This process could produce a positive correlation between average professional status and average administrative status of organizations, even though the strictly organizational-level process was absent or worked in the opposite direction.

---

[7] Random samples stratified by rank were drawn of professional and administrative personnel within agencies. Nonprofessional (e.g., clerical and custodial employees) were excluded. The sampling fraction increased with rank and decreased with organizational size in order to ensure adequate representation of higher ranking employees and smaller agencies.

Another complication is evident in regard to the changing task environment/ administrative intensity relation. Most theory asserts that an unstable task environment is a cause, not an effect, of the shape of an organization's administrative structure (Woodward, 1965). But at the individual level, the preferred specification would appear to be that incumbency in an administrative position determines the stability of one's task environment, rather than the other way around. For the present, we are forced to ignore this complexity. Since our theoretical model is specified at the organization level, the causal ordering we first stipulated seems the appropriate one to retain.

The next stage of the model takes the level of horizontal communications as dependent upon all foregoing variables in this causal sequence. While we do not doubt that communication flows are strongly shaped by the size and configuration of the administrative component in an organization, there has been some debate over the direction of this effect (Blau, 1968; Brewer, 1971; Caplow, 1964:76). We predict it is negative and, thus, stay within that tradition which sees administratively intense organizations channeling and restricting communications (Lincoln and Miller, 1979). On similar theoretical grounds, we expect the level of communications to fall with size and division of labor but to rise with professionalization and change in the task environment. Individual administrators may well communicate frequently across departments and sections, so that the individual-level effect runs contrary to the organizational effect. On the other hand, the individual-level effects of environmental change and professionalization—we would expect—would have the same signs as their organizational counterparts: individual professionals and personnel confronted with unstable work conditions are more likely to communicate with their fellows than is true of employees not faced with these circumstances (Blau, 1955; Burns and Stalker, 1961).

Finally, decision-making decentralization is the last endogenous variable determined under this model. Numerous theoretical and empirical precedents suggest the hypothesis that organizations with high rates of communications develop decentralized decision-making structures (Bacharach and Aiken, 1976; Burns and Stalker, 1961; Hage, et al., 1971). Likewise, we predict that individuals who are centrally placed in communication networks acquire influence in decision-making processes (Blau, 1955; Guetzkow, 1965). As for the relation between administrative intensity and decentralization, however, the hypothesis is less clear. Blau (1968) has argued that the proportion of managers is a prima facie index of decentralization: more managers means more persons in decision-making roles—hence, decentralization. Similarly, studies by Pugh et al. (1968), Blau and Schoenherr (1971), Child (1972), and others identify decentralization with the spread of formal decision-making roles among the membership. On the other hand, this reasoning seems incompatible with both popular and scholarly themes which view administrative intensity and centralized decision making as twin manifestations of formal bureaucracy (Downs, 1967; Weber, 1947).

Our view is that administrative intensity gives rise to decentralization only if one assumes an individual-level causal process. The more administrators in the organization, the larger the proportion of members (who are administrators) making decisions. But at the organization level, we might find an opposing effect: the greater the proportion of administrators, the less the influence on decision making of the membership as a whole. For administrators, of course, the effect of his or her individual position offsets such a loss of power, whereas the effect of the subordinate's status is to enhance it.

This reasoning seems consistent with certain strands of organizational theory. Formal bureaucracy decentralizes in the sense that it divides decision-making responsibilities into specialized roles and delegates these to official positions (Child, 1973; Weber, 1947). But this same process of formal differentiation and delegation means that rank-and-file members who might have had some input to the decision, before it became an official function, now have less. Similarly, the administrator's own power is circumscribed as the number of officials holding responsibilities for specialized decisions grows (Crozier, 1964). The case of traditional Japanese management is instructive here to illustrate that delegation of formal authority and decentralization of decision making need not be the same. Yoshino (1968) describes the *ringi* system as a decision-making practice in which little formal authority is delegated but participation is widespread. Such participation takes the form not of individuals carrying out their separate assigned decision-making roles, but of a cooperative, consensus-seeking group process involving many members in each decision to arise.

Following this same line of thought, we also deviate from the findings of Blau and Schoenherr (1971) and Pugh et al. (1968) and predict that division of labor—while having a positive effect on administrative intensity—has a negative effect on decentralization: the greater the differentiation of functional roles in the organization, the less involvement by the general membership in decisions. Similarly, increasing organizational scale diminishes the breadth of collective involvement in organizational decisions. By contrast, we follow Burns and Stalker (1961) in viewing a changing task environment and professionalization as forces making centralized decision making ill-adapted to organizational goals. Organizations subject to changing environments and possessing professional staffs are more likely to make decisions through fluid, unstructured consultations. Any individual-level effects of these two properties we believe to be in the same direction. Certainly professional status and expertise are resources which organizational members convert easily to power in organizations. And Crozier's (1964) famous discussion of the maintenance workers in the French tobacco firm offers classic testimony for the proposition that individuals responsible for unstable and changing domains acquire informal organizational power.

Analysis and Findings

Table 1 presents zero-order correlations and univariate statistics for the measures we examine. As we will not have further opportunity to consider the associations among exogenous variables in our model, we should make certain observations now. Overall, this pattern of relations is consistent with the "mechanistic-organic" or "bureaucratic-professional" dimensions often seen to underlie structural variability in organizations (Blau and Scott, 1962; Burns and Stalker, 1961; Hage, 1965). Size and division of labor, as virtually every previous study has shown (e.g., Blau and Schoenherr, 1971), are highly correlated, and both reveal mild inverse correlations with professionaliza-

Table 1. Zero-Order Correlations and Summary Statistics

	2	3	4	5	6	7	$\bar{X}$	SD	E^2

tion. Professionalization, in turn, is positively correlated with task environment change (Comstock and Scott, 1977). The exception to this pattern is the likewise-positive correlation between size and CHANGE. Received theory generally views large organizations as operating in stable task environments (Starbuck, 1965).

The other information worth noting in Table 1 is the column of correlation ratios (E^2). These indicate proportions of total variation in respondent reports which lie between organizations. That they have certain implications for our ability to generate stable estimates of $b_{\bar{Y}\bar{X}}$ and b_{yx} should be evident from the extreme cases where all variation is either between (as with size and division of labor) or within organizations.[8] They range from less than 5% of the total individual variation in perceived change to 18% of that in reported communications. We do not attach great importance to the fact that these values appear low. First, our interest is confined to the between-organizations variation. Patterns involving these variables within organizations are of interest only insofar as their form also describes a component of the between-organizations pattern. Secondly, we do not attribute intraorganizational variation to perceptual error. Should we do so, such low E^2's might be cause for concern with the quality of our measurement. Thus, R. B. Duncan (1972) defends the perceptual measures of environmental uncertainty he employs by noting the large fractions of organizational variance they display. Our aggregate measures have valid analogues for individuals, however, and we interpret the latter's variation substantively.

In the ANCOVA model (see Figure 2), the total relation between $\bar{X}_j$ (or a set of $\bar{X}_j$'s) and $\bar{Y}_j$ operates through two constituent processes. First there is C, the "compositional" or individual-level component: the organizational mean of Y predicted from the regression of $\bar{Y}_j$ on $\bar{X}_j$ under the assumption that the average within-group slope sufficed to capture the relation of Y to its causes at both individual and organization levels. The second component, R, is a residual (Hauser, 1971:chap. 2): the difference between the $\bar{Y}_j$ and its C component. Unlike C, which is an exact linear function of the $\bar{X}_j$'s, R combines the effects of the $\bar{X}_j$ (as organization-level or "structural" effects) with variation originating from unspecified sources (a disturbance term). It is instructive, then, to evaluate the relative importance of these components by partitioning the total variance in each endogenous variable into the fractions derived from these sources. Table 2 presents this decomposition.

While we have not carried a torch for organization-level explanations in this investigation, we nonetheless note with interest that in two out of three comparisons they seem more powerful than explanations favoring individual-level processes in accounting for our dependent variables. Table 2 shows the organizational- and individual-level components of the variance in decentralization to be roughly equal. The organizational contributions to administrative intensity and communications, however, exceed their individual-level counterparts by substantial margins. (We should bear in mind, however, that the presence of global measures as independent variables means they necessarily contribute nothing to the individual-level variance component.) The joint component is variation due to an inseparable composite of individual and organizational effects (see Duncan et al., 1972:195). The residual component—that explained by neither of these sources—ranges from 19% (decentralization) to 75% (administrative intensity).

If Table 2 underscores the importance

Table 2. Decomposition of Variance

	Component			
Dependent Variable	Organizational	Individual	Joint	Residual
ADMIN	.217	.092	−.054	.745
COMMUN	.393	.053	.043	.511
DECENT	.245	.278	.290	.187

Note: Table entries are proportions of total variance attributable to each source.

---

[8] The issue here is the familiar one that limiting the variance in a regressor increases its standard error. Where values of E^2 are low, between-organization effects will be estimated less reliably.

Table 3. Estimates of Total and Component Effect Parameters

		Predetermined Variables

Note: P=standardized coefficient, b=unstandardized coefficient, SE(b) standard error of b. Standard errors of individual and organization component coefficients are equal to SE(b)'s total coefficients. Component effects are *indirect effects* on each dependent variable as mediated through C and R terms (see Figure 2).

* Coefficient exceeds its standard error.

of organization-level processes in our data, it leaves ambiguous their nature and how they differ from contributing individual-level patterns. Again consider Figure 2. It shows that the total effect of $\bar{X}_j$ on $\bar{Y}_j$ is the sum of two indirect effects, one representing the organization-level causal process, the other representing the individual-level process. Applying the path analysis convention for partitioning total effects, we see that $P_{\bar{Y}\bar{X}} = P_{C\bar{X}}P_{\bar{Y}C} + P_{R\bar{X}}P_{\bar{Y}R}$. Table 3 applies such a partitioning procedure to our data. First presented for each dependent variable are the total effects of antecedent organizational properties. Subsequent rows present individual-level and organization-level components of the total effect. Note that both unstandardized and standardized component coefficients sum (within rounding error) to their corresponding total effects. Also note that the standard errors of the component effects equal the standard errors of the total effects.[9] With only twenty organizations, we adopt a weak criterion of statistical significance: whether a coefficient exceeds its standard error. As Rao and Miller (1971:37) have observed, variables whose coefficients fall short of this criterion impair, rather than enhance, prediction, for they produce decrements to the adjusted R^2. Finally, Table 3 demonstrates our earlier point that any effects of global variables must operate through an organization-level process: the individual-level effects of size and division of labor are null, while the corresponding organizational effects equal the total effects.

---

[9] We determined the equality of the three component effects' standard errors through an inductive procedure. If $1-R^2_{\bar{X}}$ is the proportion of variation in $\bar{X}_j$ which is unexplained by other independent variables, then $(1-R_{\bar{X}}^2)(P_{R\bar{X}}P_{\bar{Y}R})^2$ is the unique contribution made by $\bar{X}_j$ to the variation in $\bar{Y}_j$ through an *organization-level* process. $(1-R^2_{\bar{X}})(P_{c\bar{X}}P_{\bar{Y}C})^2$ is the analogous contribution through an *individual-level* process. When either quantity is divided by $1-R^2_{\bar{Y}}/N-k$ (where $N-k$ is degrees of freedom), we have an F-ratio which, in conjunction with the metric coefficients for the organization- and individual-level effects, can be solved for these coefficients' standard errors: $SE(b) = b/\sqrt{F}$. As an example, consider the effect of COMMUN on DECENT. For the organization-level component, we have: $(.511)(.234)^2 = .0279$. For the individual-level component, we have: $(.511)(.185)^2 = .0175$. The denominator of the F-ratio is: $1-R^2_{\bar{Y}}/N-k = .187/13 = .0144$. Then $F_o = .0279/.0144 = 1.938$ and $F_I = .0175/.0144 = 1.215$. Taking square roots and dividing into the metric coefficients gives us: $.0184/\sqrt{1.938} = .0146/\sqrt{1.215} = .0132$ which proves to be the standard error of the "total" coefficient as well.

We begin our review of this evidence by considering total effects on administrative intensity. Readily apparent is its negative dependence on size, which the majority of investigators researching this relation have also found. In our data, however, division of labor fails to reveal the positive connection to administrative overhead which others have reported (e.g., Blau, 1970). Both task environment change and professionalization have significant influences on administrative intensity, but these diverge in direction. Professionalization, as hypothesized, reduces an organization's propensity to generate administrative positions. Contrary to images of the "organic" organization (Burns and Stalker, 1961; Hage, 1965), however, we find that a changing task environment raises the proportion of administrators. This result is reminiscent, perhaps, of Crozier's (1964) suggestion that bureaucracies respond to uncertainty by building in new administrative roles and other formal structures to eliminate it.

Now let us see what new insights may be introduced by decomposing the aggregate effects of change and professionalization into their constituent individual-level and organization-level components. We conclude that the positive influence of change on administration derives entirely from an organization-level process. The organization-level effect of this variable is nearly identical to its total effect, while the individual-level contribution is miniscule. This outcome warrants confidence in the causal ordering we specified between these variables and in the supposition that this perceptual measure can validly tap an organizational property.

Professionalization's influence on administration conforms closely to our predictions. The negative total effect proves to mask strikingly different individual and organizational patterns. The negative effect recurs at the organization level. But at the individual level we find a pronounced positive impact. These findings have considerable intuitive appeal. Individuals with high scores on the professionalism scale are, unsurprisingly, more likely to wield supervisory power. Holding constant this pattern, however, professionalization depresses the proportion of supervisory personnel. The latter tendency is strongly supportive of the venerable proposition that "bureaucracy" and "professionalism" are alternative, incompatible modes of organization (Blau and Scott, 1962).

Now consider the total and component effects on communications, which we take to be a function of these same exogenous determinants plus administrative intensity. The estimated total effects do not conform well to our hypothesis. We predicted the negative influence of size on communications: the ease with which information flows among organizational subunits declines as the number of members grows (Graicunas, 1937). But we observe a strong positive effect of division of labor—an outcome discordant with Burns and Stalker's (1961) view that lateral communications intensify when official roles are less differentiated and formally defined. Furthermore, neither a changing task environment nor professionalization has more than a slight (and nonsignificant) influence on communications, although both are regularly seen as forces causing flexible structures and horizontal exchanges (Burns and Stalker, 1961; Hage et al., 1971). The final surprise is that administrative intensity displays a strong positive relationship with communications flow. We hypothesized the opposite, assuming that a large administrative component meant that communications were more likely to be confined to vertical channels.

Our impressions do change somewhat when the component processes generating these patterns are taken into account, but the general picture at the organization level remains substantially the same. The negative effect of size and the positive effect of division of labor are necessarily replicated, but so are the null estimates of the influences of change and professionalization. On the other hand, the individual-level effect of administrative intensity—while positive—is trivial, and we observe a positive influence of professionalism which almost satisfies our statistical decision rule. A reasonable interpretation of these results might be: while individual professionals are more likely to engage in lateral communications than administrators, professionalization as an organizational process does not facilitate communications flow.[10] Administrative intensity, however, is a rather powerful determinant of such flows.

The final variable explained by the present model is decentralization. The pattern here is essentially the anticipated one. Both size and division of labor are inversely related to average decision-making participation, although these effects are small and marginally significant. The positive effect of task environment change is equally small. The coefficient estimated for administrative intensity is judged within sampling error of zero by our criterion. Yet both professionalization and communications are rather strongly linked to decentralization in the hypothesized direction: High communication rates and a professionalized work force engender decentralized decision making.

Once again, we learn considerably more about the processes underlying these patterns when we partition them into organizational and individual components. Professionalization, communications, and change have positive effects at both individual and organizational levels. It is, thus, not merely the case that professional organizations are decentralized because individual professionals within them are more likely to be involved in decisions. That process operates, but it is paralleled by one at the organization level: as the proportion of professionals rises, all employees experience an increase in influence. A similar interpretation is warranted concerning the micro- and macroeffects of communications and change; the total effects of both are divided almost evenly between compatible organizational- and individual-level processes.

Finally, the organizational- and individual-level influences which administrative intensity is shown to have on decentralization are perhaps the most noteworthy of these findings. We would indeed be surprised if persons in positions of formal supervisory authority did not participate in decisions more than colleagues not so officially advantaged. The individual-level results do reveal that administrative status has the single greatest impact on decision-making involvement. Yet the organizational effect is *negative*: organizations with large administrative components appear to centralize decision making in relatively fewer hands.

This is an intriguing finding which we think clarifies certain contradictory themes in the comparative research literature on organizations. To review our earlier argument, we might, in the face of these results, be disinclined to accept the "revisionist" argument which arose from the findings of Blau and Schoenherr (1971), the Aston Group (Pugh et al., 1968), and Child (1972) concerning bureaucracy and centralization (see Aldrich, 1979:11; Blau, 1970; Child, 1973). While early comparative analysts of organizations (Hage and Aiken, 1967; Hall, 1963; Pugh et al., 1968) had inferred from Weber (1947) that highly structured and formal organizations centralize decision-making at high levels, evidence soon accumulated that centralization was characteristic of simpler, less bureaucratic, organizations. Researchers encountering this finding, however, measured centralization essentially as the opposite of administrative intensity: highly centralized organizations were those in which a relatively small proportion of the membership performed formal decision-making roles. Assuming an individual-level process, administratively intense organizations are indeed decentralized: as more participants in organizations acquire supervisory authority, those persons add to the number making inputs to decisions, and influence spreads. But our data suggest that growth in the administrative component has an opposite "structural" effect: if A's becoming a supervisor means that B's power is diminished, a process of centralization is at work as well. By focusing on the distribution of formal authority, while neglecting that of actual participation in decisions, organizational research, we suspect, has obscured key issues in organizational theory.

---

[10] Again we should stress that, while we discuss our results here and elsewhere in terms of "organizational-level" and "individual-level" processes, we consider individual-level, within-organization effects only insofar as they describe a component of the between-organizations covariation (see Figure 2).

Conclusions

Aggregate indicators of organizational properties have been subject to much criticism and held to be poor substitutes for "global" measures. Yet we have shown that they permit insights into organizational phenomena which global indicators do not make available. It has long been recognized that an observed association between organizational traits can arise through a variety of processes at multiple levels. In general, however, organizational theory has emphasized organization-level effects and regarded them as something distinct from the aggregation of relations observable for individuals. This is particularly true of sociological approaches to organizational study in the late 1960s and 1970s. The Durkheimian dictum that sociologists should find their subject matter in properties of collectivities which are not reducible to those of individuals has nowhere been taken more seriously than by organizational sociologists who have insisted that organizations should be units of analysis—not merely contexts for studying individual or interpersonal behavior—and that organizational theory should address itself to developing propositions which hold at that macrolevel and not necessarily below it (see, for example, Perrow, 1972).[11]

Although not methodological Durkheimians in the sense of holding individual explanations to be irrelevant to our scientific mission, we do believe it is often at least informative and occasionally it is crucial (as when individual-level effects are viewed as measurement error) to determine whether observed associations among organizational properties have organizational versus individual origins. The methods we have discussed and applied seem an effective means of making that determination. Moreover, we do not believe that merely because we measured organizational variables as means of individual-level distributions we have sacrificed validity. Such measurement, as we pointed out, may not always be valid or appropriate, but its widespread use in organizational research suggests that it often seems so to investigators faced with concrete measurement tasks. Our recommendation is simply that researchers take advantage of these properties of aggregate measurement to extract meaning from their data which they have neglected in the past.

Also, we do not intend our own data analyses to be merely illustrative of our techniques. Our findings speak to several current and important issues in organizational theory and research. Without reviewing all that has gone before, certain key findings should be underscored. As Comstock and Scott (1977) discuss, the level of analysis at which an unstable task environment is believed to produce its effects on organizational structure varies among treatments of this topic in the literature. Hickson et al. (1969), for example, suggested that the weak influence of technology on most structural measures, which they found, might be due to an improper level of aggregation. They concluded that structural changes in response to technical variations were most pronounced for organizational components closest to the workflow. Similarly, Comstock and Scott (1977) found stronger effects of task variability at levels of aggregation lower than that of the organization as a whole. Our results diverge from these precedents, however; for the strongest effect of a changing task environment we find—that giving rise to increased administrative intensity—is wholly an organization-level one.

---

[11] We have dealt here only with organizational and individual levels of aggregation but, as some of our examples suggest, other levels (e.g., departments, administrative strata) are often of interest to organizational researchers as well. Clearly, however, an attempt to apply in the same analysis the methods we discuss to more than two levels of aggregation would run into technical complexities beyond the scope of our paper.

The portrait we painted of organizations with high communication flows is at odds with our own expectations and with the impressions left by past research. An extensive division of labor and a large administrative component—properties reminiscent of traditional bureaucracy—were strongly related through organizational processes to heightened communication flows. Professionalization and a changing task environment—factors which, on theoretical grounds, we expected would increase communications—did so only through an individual-level channel in the former case and in the latter case not at all.

Finally, our findings regarding decentralization support an earlier conception of bureaucracy as compared with that which has grown out of recent studies measuring decentralization as delegation of formal authority. That is, we find organizations with high average levels of decision-making participation to be small, less differentiated, professionalized, prone to lateral communications, and more likely to be found in changing task environments. Furthermore, net of the tendency for individual administrators to make decisions, participatory organizations prove to have relatively small administrative components. Although the limitations of our data base preclude strong inferences, we would nonetheless hope that these findings, combined with our discussion of aggregation issues, occasions some reexamination of the decentralization question in organizational research.

APPENDIX

MEASURES OF VARIABLES

1. SIZE: total employment size transformed to its natural logarithm.

2. DIVLAB: total number of occupational titles.

3. CHANGE: perceived change and uncertainty in tasks and work environment. Mean of the response codes to the following six items. Cronbach's Alpha = .492.

   a. How much change has there been in your job or position during the last year? (no change = 1, complete change = 5).

   b. How often are there changes in the social, economic, or political conditions outside your organization which affect your work? (never = 1, always = 5).

   c. People can often point to prevailing ideas in the community or in their profession about the best methods or techniques to be used in their job. How often are there changes in such ideas regarding your work? (never = 1, always = 5).

   d. How often are you certain of the requirements or methods to be used in your work? (never = 1, always = 5).

   e. How often do you encounter new types of problems in your work? (never = 1, always = 5).

   f. How often do you apply new techniques or methods in doing your job? (never = 1, always = 5).

4. PROFES: professionalization. The sum of responses to the following three items:

   a. How many professional or occupational associations do you belong to?

   b. During the past two years, how many meetings of professional or occupational associations have you attended?

   c. During the past two years, how many professional or occupational journals have you read on a somewhat regular basis?

5. ADMIN: administrative intensity. A dummy variable indicating whether or not the respondent was responsible for supervising the work of others.

6. COMMUN: interdepartmental communications. The respondent's estimate of the number of individual contacts or conferences he or she had with persons outside his or her department in an average week.

7. DECENT: decentralization of decision making. The mean of the response codes (never = 1, always = 5) to the following six items. Alpha = .85.

How frequently during the past year did you participate in the following decisions in your organization?

   a. on personnel matters (hiring, firing, and promotion).

   b. on approval of budgets.

   c. on approval of new policies and goals.

   d. on adoptions of new programs.

   e. on handling public relations outside your organization.

   f. on establishing joint or cooperative programs with other agencies.

Note: With the exception of size and division of labor, organizational scores on these variables were computed as unweighted means of respondents' scores.

MEAD AND BLUMER: THE CONVERGENT METHODOLOGICAL PERSPECTIVES OF SOCIAL BEHAVIORISM AND SYMBOLIC INTERACTIONISM*

HERBERT BLUMER
University of California, Berkeley

American Sociological Review 1980, Vol. 45 (June:409–419)

The article, "Mead vs. Blumer. . ." (*American Sociological Review*, June, 1979), carries serious misrepresentations. The authors, Clark McPhail and Cynthia Rexroat, have given an erroneous picture of (a) Blumer's view of social reality, (b) Blumer's view of naturalistic study, (c) Mead's view of scientific method, and (d) Mead's view of social behavior. Their misrepresentations arise from an effort to reduce Mead's thought to a much narrower scheme of how human social behavior should be studied.

Introduction

Scholarship in any important controversial area, such as that of the theoretical position of symbolic interactionism, should not have to carry the additional burden of misrepresentation. It is for this reason that I wish to correct the inaccurate depictions that are advanced in the article, "Mead vs. Blumer: The Divergent Methodological Perspectives of Social Behaviorism and Symbolic Interactionism" (McPhail and Rexroat, 1979:449–67). The authors, Clark McPhail and Cynthia Rexroat, proclaim that there is a basic difference, indeed a profound contradiction, between the views of George Herbert Mead on "social behaviorism" and my views on "symbolic interactionism." Their effort to establish this thesis is flawed by serious misrepresentations. I wish to call attention to these misrepresentations.

THE MCPHAIL-REXROAT ARGUMENT

The McPhail-Rexroat argument has three parts. (1) They contend that there is a basic difference between the methodological scheme of Mead's "social behaviorism" and my scheme of "symbolic interactionism." (2) They assert that this alleged difference in methodology springs, in turn, from a fundamental ontological difference between my views of "reality" and those of Mead. (3) Finally, they present several instances of research (McPhail and Rexroat, 1979:460–5) which, they declare, exemplify the proper nature of social investigation according to Mead's methodological views. I wish to consider each of these three parts of their argument. I will take up first, however, their second allegation, that of an ontological difference.

Alleged Ontological Difference

McPhail and Rexroat declare that: (a) whereas Mead adopts a pragmatic stance, my pragmatic stance "bears no resemblance to Mead's position" (McPhail and Rexroat, 1979:459); (b) whereas Mead sees scientific study as leading to a recasting of the world, I see such study as merely disclosing in an Aristotelian manner the fixed nature of the given reality; (c) whereas Mead recognizes that reality in its "objective" form requires a shared perspective, or what McPhail and Rexroat label "convergent responses," I fail to recognize this requirement; and (d) whereas Mead saw the scientific act as a social act shared by investigators, I see it as solely an individual act. I wish to consider each of these four contentions.

(a) McPhail and Rexroat declare that, contrary to Mead, whose philosophical position is that of pragmatism, I "waffle" or "vacillate" between the positions of realism and idealism. They see this alleged waffling in that I recognize a "reality" which is "out there," a reality which has a "nature" that is to be "discovered"; this, according to McPhail-Rexroat, puts me in the camp of realism. However, they assert that my view to the effect that "the world depends on how it is perceived" beds me in the camp of idealism. In the eyes of the authors this alleged vacillation not only places me in opposition to Mead's pragmatic stance but also introduces a "paradox" or contradiction into my ontological position.

---

* Direct all correspondence to: Herbert Blumer; Department of Sociology; University of California; Berkeley, CA 93720.

The inaccuracies in this characterization are shown by noting the following basic tenets of Mead's pragmatism:

1. There is a world of reality "out there" that stands over against human beings and that is capable of resisting actions toward it;
2. This world of reality becomes known to human beings *only* in the form in which it is perceived by human beings;
3. Thus, this reality changes as human beings develop new perceptions of it; and
4. The resistance of the world to perceptions of it is the test of the validity of the perceptions.

These tenets signify that, *in opposition to the idealist position,* there is a real world "out there" which may not be perceived at all by human beings or which may be perceived incorrectly. The tenets signify, *in opposition to the realist position,* that the real world does not have a basic intrinsic, fixed makeup but may change as human beings reconstruct their perceptions of it. The linking of "perception" with something "out there," that thereby comes to be perceived, is not "waffling"; nor is it "paradoxical." Instead of being contrary to Mead's position, it is Mead's position.

(b) In the case of their second ontological charge, McPhail and Rexroat use several of my literary expressions to attribute to me an utterly inapplicable Aristotelian view of reality. In my writings on the scientific study of ongoing group life, I have spoken of the need to "lift the veils" from what is hidden, or to "discover the nature" of what is thereby revealed, or to "dig out [data] by careful empirical scrutiny." McPhail and Rexroat gratuitously conclude that in using these expressions I am thereby designating the existence of an implanted, fixed, and eternal "reality," in opposition to the changeable reality in Mead's pragmatic stance. This conclusion is without foundation. Let me quote the relevant portion of my original discussion:

> . . . the study of [ongoing group life] requires us to expand and deepen our perception of it . . . . The metaphor that I like is that of lifting the veils that obscure or hide what is going on . . . . The veils are lifted by getting close to the area and by digging deep into it through careful study. . . . How does one get close to the empirical social world and dig deeply into it? This is not a simple matter of just approaching a given area and looking at it. It is a tough job requiring a high order of careful and honest probing, creative yet disciplined imagination, resourcefulness and flexibility in study, pondering over what one is finding and a constant readiness to *test and recast one's views and images of the area.* . . . It is particularly important in exploratory research for the scholar to be constantly alert to *the need of testing and revising his images, beliefs, and* conceptions of the area of life he is studying. (Blumer, 1969:39–41. My new emphasis.)

The quoted statements show that, contrary to the picture that McPhail and Rexroat are striving to present, the expressions I was using do not imply a fixed, unchangeable reality but, instead, one that is obviously always open to being recast as investigators approach its study with new perspectives.

(c) McPhail and Rexroat's (see p. 458, first [top] paragraph) third contention in support of their ontological allegation is that, contrary to Mead's view of reality, my view does not allow or provide for the sharing of perspectives—something that is necessary for the "objective reality of perspectives." This contention reflects serious misunderstanding; it amounts to a charge that, contrary to Mead's view of reality as socially shared, I hold and propose a view of reality that is solipsistic. Anyone who reads intelligently and carefully my discussion of objects and of how they are formed through the process of shared social interaction could not possibly attribute to me a solipsistic view of reality (See Blumer, 1969:10–12).

(d) The last "ontological" argument given by McPhail and Rexroat is not ontological but is actually a *methodological* argument. The argument reads:

> Blumer fails to recognize Mead's requirements that exceptional facts and their circumstances be so described by the initial investigator that others will experience the facts and that the investigator's working hypothesis be set forth and corroborated by others. (McPhail and Rexroat, 1979:458)

This methodological charge is false, as I will show, shortly, in the discussion of alleged methodological differences between Mead and me.

I trust that the foregoing discussion will make students and critics of symbolic interactionism aware of the serious misrepresentations that are contained in the McPhail-Rexroat allegations of ontological differences between Mead and me. No one of their contentions is true.

Alleged Methodological Difference

In seeking to specify their charge of an opposition between Mead's *methodological* perspective and mine, McPhail and Rexroat assert that Mead and I differ with regard to: (1) how we view the antecedents and the initiation of scientific inquiry, (2) how we treat the development and examination of hypotheses, and (3) how we treat the consequences of scientific inquiry. I wish to discuss each of these three lines of argument on which they base their case.

(1) Alleged differences in the viewing of antecedents and the initiation of scientific inquiry. The first part of this portion of McPhail and Rexroat's argument is that Mead and I differ in our views of the "antecedents of scientific inquiry." Yet, as the reader of their article will note, they actually assert no difference between Mead and me on this point except that my characterization and analysis is "erratic." Aside from the legitimate question of whether being "erratic" establishes a basic difference, it is odd to see how McPhail and Rexroat try to show that I am "erratic." To establish this charge they (p. 451) say, "On the one hand he [Blumer] is less sanguine than Mead with the adequacy of existing behavioral scientific theories, laws and beliefs" and, on the other hand Blumer "warns investigators to beware 'imprisonment' by their antecedent theoretical schemes." I am unable to understand how some sort of a combination of my being less "sanguine" than Mead and of my "warning" to investigators establishes me as being "erratic." While having no relation to this puzzling argument, I would like to add that no one knows whether I am more or less "sanguine" than Mead on the matter in question; also, Mead, as well as multitudes of other philosophers of science, would agree with me in recognizing that scientific investigators may become "imprisoned" by their antecedent views. Obviously, McPhail and Rexroat have done nothing to establish a difference between the way in which Mead and I view the "antecedents of scientific inquiry."

The allegation of a difference between Mead and me with regard to the "initiation of scientific inquiry" is stated by McPhail and Rexroat (1979:451–2) to be: "But Mead, unlike Blumer, requires and discusses procedures for the controlled perception of observed facts and for establishing problems as social objects" (p. 452).[1] Stated more precisely, this seems to mean that the method of study which I propose does not allow or require the investigator to identify his problem, his data, and his ideas in such a way that other investigators can check what he says. This charge by McPhail and Rexroat is completely wrong. Let us examine this matter in some detail, since it is pressed vigorously by McPhail and Rexroat. They are referring to my treatment of "exploration" and "inspection" as the two parts of the process which I proposed for the "naturalistic" study of human conduct and human group life. By "naturalistic" study I mean the study of conduct and group life as these occur naturally in the everyday existence of people—in the interaction of people as they associate in their daily lives, as they engage in the variety of activities needed to meet the situations that confront them in their day-to-day existence. This natural makeup of human conduct and group life covers what is done by individuals, organizations, institutions, communities, and collectivities as they carry on their lives. It comprises what Mead spoke of so frequently in his lectures as the "stuff" of human society—the complex of ongoing social acts that, according to Mead, constitutes the social life of human societies. This natural social world is the empirical domain of social science, the domain out of which problems arise, and the domain which is the test of the validity of their analysis.

---

[1] Mead did not deal in his writings or his lectures with the methodological problems involved in applying his scheme to the study of human conduct and human group life. He is frightfully shy in telling us how to study the social or joint act, which he set up as the basic unit of human group life. He did not tell us how to proceed to study the "generalized other" as it operates in the case of given individuals or groups in given situations. He did not tell us how to study the self-interaction which, let us say, a prospective bank embezzler is carrying on with himself prior to committing his embezzlement. He did not tell us how, as social scientists, we should proceed to take the roles of those we are studying, or what we should do to be sure that we are taking their roles. He did not tell us how to study the ways in which the human actor constructs his act. With brilliant insight, Mead identified the basic character of human social interaction, of self-interaction, of the joint or shared makeup of human group life, and of the emerging nature of individual and social acts. But he did *not* inform us how to proceed to study these basic matters. This picture is in utter contradiction to what McPhail and Rexroat (1979:452) declare: "But Mead, unlike Blumer, requires and *discusses* procedures for the controlled perception of observed facts and for establishing scientific problems as social objects" (my emphasis). *Where* does Mead discuss these procedures for the study of human social behavior?

Now I have called attention to the fact that (following Mead) this empirical domain of human group life is caught up in a continuous process of formation as people have to adjust to one another and to the situations with which they are faced. This means two things of great significance in the case of social science: (1) Much of what develops in human group life, especially in complex societies, is obscure or hidden from immediate notice; and (2) social scientists are *not* likely to have an initial firsthand, intimate familiarity with the empirical areas of group life that they propose to study. Because of these two conditions, I advocated and stressed the need of exploratory study (Blumer, 1969:40–2). Such exploratory study permits a research scholar "to form a close and comprehensive acquaintance with a sphere of life that is unfamiliar and hence unknown to him" and it is "the means of developing and sharpening his inquiry so that his problems, his direction of inquiry, data, analytical relations and interpretations arise out of and remain grounded in the empirical life under study." It is clear that "exploration," as I see it, is to be used in place of studies in which the research scholar has no close familiarity with, or knowledge of, his empirical area of concern. The purpose of exploration is to make sure that his perception of his field and the problem that he sets up are empirically grounded instead of being fashioned out of inadequate or faulty knowledge.

"Inspection" is the label I have used for the subsequent part of scientific inquiry, namely the exacting study of the problem that arises out of exploration. Since the stage of inspection is particularly the target of McPhail and Rexroat's (1979) attempt at criticism, it is desirable to see how I described it. Thus I introduce here a quote from my article:

> By "inspection" I mean an intensive focused examination of the empirical content of whatever analytical elements are used for purposes of analysis, and this same kind of examination of the empirical nature of the relations between such elements. Let me explain this abstract statement. By analytical elements I have in mind whatever general or categorical items are employed as the key items in the analysis, such as integration, social mobility, assimilation, charismatic leadership, bureaucratic relation, authority system, suppression of dissent, morale, relative deprivation, attitudes, and institutional commitment. As the examples suggest, such analytical elements may refer to processes, organization, relations, networks of relations, states of being, elements of personal organization, and happenings. These analytical elements may be cast in different degrees of generality, ranging from something very broad such as integration to something more restricted such as mobility aspiration in the case of urban Negro adolescents. The procedure of inspection is to subject such analytical elements to meticulous examination by careful, flexible scrutiny of the empirical instances covered by the analytical element. The empirical instances are those that appear in the area under study; their careful, flexible scrutiny is done in the

> context of the area in which they take place. Thus in the case of an analytical element such as assimilation, referring let us say to the assimilation of girls into organized prostitution, the empirical instances would consist, of course, of the separate careers of girls undergoing such assimilation. The careful scrutiny of such instances with an eye to disengaging the generic nature of such assimilation represents what I have in mind by "inspection." (Blumer, 1969:43–4)

With this brief reminder of what is meant by "exploration" and "inspection" as making up the *naturalistic* study of human group life, let me return to McPhail and Rexroat's (1979) argument. They are asserting that exploration and inspection, as I have defined them, do not allow the research scholar to describe his problem, his leading ideas, his mode of inquiry, and his data in such a way that other investigators can check on what he presents. Such a contention has no foundation. There is nothing in exploration and inspection to prevent the investigator from describing the question he has raised, the problem he has set, the ideas that guide his inquiry, his sources of data, the nature of the data, and the interpretations that he makes—all in such a way that other investigators can review what he has done and can examine the empirical world to see whether the account stands up. Indeed, this has been done in multitudes of naturalistic studies ranging from monographic studies of fauna and flora, in biology, through hundreds of anthropological monographs of so-called primitive societies, and scores of well-known sociological studies, such as Thomas and Znaniecki's (1927) *Polish Peasant*, Park and Miller's (1921) *Old World Traits Transplanted*, Thrasher's (1927) *The Gang*, and Wirth's (1928) *The Ghetto*. Such studies were naturalistic studies, using primarily the methods of exploration and inspection. They were presented in such form as to definitely allow other research scholars to reexamine what is claimed by the original investigator, to see whether the account is empirically correct. For McPhail and Rexroat to assert, in effect, that "exploration" and "inspection" can yield only solipsistic accounts that are incapable of test or corroboration shows a misunderstanding of the nature of naturalistic study and ignores a vast body of literature.

(2) Alleged differences in the treatment of hypotheses. The second methodological claim advanced by McPhail and Rexroat (1979:452–5) is that Mead and I differ in how we treat "hypotheses" in scientific inquiry. They seek to build their case on the following arguments:

1. "Blumer avoids the term *hypotheses.*" (p. 453)
2. For Blumer, the "meaningful connection between components *in the empirical world*" is "not assigned or hypothesized. It is discovered." (p. 453)
3. "Whereas Mead's treatment of hypotheses is theoretically grounded, though not formally deductive, Blumer's treatment is virtually atheoretical, inductive empiricism." (p. 453)
4. "Blumer rejects 'the four customary means' of empirically validating relationships between analytical components." "In short Blumer rejects all that Mead requires." (p. 454)
5. Mead "did not construe observation as a matter of recording 'the natural ongoing character' of things. . . . Rather, observation is guided by the problems and interests of the investigators." (p. 454)
6. "The investigator must specify the conditions to be met and the actions to be taken such that others, through their conduct, can experience, must observe, can confirm or reject the reported observations of the investigator." (p. 454)

I will briefly discuss each of these arguments, using the same numbers for identification.

1. I did not avoid the term "hypothesis." I merely used other words, such as "ideas," "leading ideas," "premises," "postulates," and so forth, just as Mead did in a very liberal fashion. (See, for example, [Mead, 1936:268–74] his discussion in *Movements of Thought in the Nineteenth Century.*)

2. As my earlier ontological discussion in the present article should have made clear, the second argument here by McPhail and Rexroat has no ground. To juxtapose "discovery" and "hypotheses" is unwarranted. It is thoroughly possible to make a "discovery" by following out a hypothesis, and it is thoroughly possible to treat a "discovery" as hypothetical.

3. The third argument is similarly false. I have made it clear that, in the case of both "exploration" and "inspection," the investigator necessarily has to guide himself by sets of ideas in seeking to carve out his problem, to get his data, and to analyze relations.

4. The fourth argument of McPhail and Rexroat is the result of a faulty reading by them of my discussion (Blumer, 1969:27–33) of four conventional methods of study: adhering to a scientific protocol; engaging in replication of research studies; relying on the testing of hypotheses; and employing so-called operational procedures. As a careful reading of what I wrote will show, I criticized these four methods *when they are used as substitutes* for the meticulous examination of the empirical area under study. McPhail and Rexroat have ignored this restriction and have extended my criticism to apply to all studies! This regrettable misinterpretation can be illustrated specifically in the case of the "testing of a hypothesis." I was at pains to point out in my discussion (pp. 29–30) that I was criticizing a widely held procedure—the procedure of (a) starting with a preestablished model whose premises have not been empirically validated and of (b) seeking to validate *the model* by testing a hypothesis deduced from the model. In my discussion I was not denying the need of testing hypotheses; I was denying the value of testing hypotheses as the means of establishing the validity of premises when the premises, themselves, had not been empirically tested. McPhail and Rexroat have failed to catch the point of the discussion.

5. The fifth McPhail-Rexroat argument is to the effect that the research scholar engaging in exploration and inspection has no problems or interests to guide his observations. As I have already explained, this is a false understanding of what takes place in naturalistic study.

6. The sixth argument by McPhail and Rexroat is another repetition of their claim that exploration and inspection do not permit the research scholar to describe his study so that it is open to test and corroboration by others. As I have pointed out above, this claim flies in the face of a mass of naturalistic studies in the fields of biology, anthropology, and sociology which have relied on exploration and inspection.

I have to conclude that there is nothing in the McPhail-Rexroat arguments to show their claimed difference in the ways in which Mead and I view the use of hypotheses in scientific inquiry.

(3) Alleged differences in the consequences of scientific inquiry. McPhail and Rexroat (1979:455) present their third alleged methodological difference between Mead and me in the statement that "Blumer's treatment of the theoretical consequences of inquiry is as equivocal as his discussion of the theoretical antecedents." I have already shown the meaningless character of the claim that I was "erratic" in the case of the "antecedents of scientific inquiry" (see discussion [*1*], earlier). Similarly, their claim here that I am "equivocal" with regard to the consequences of scientific inquiry has no meaningful foundation. The equivocation which they claim is that, on the one hand, for me, "every object of empirical consideration has a distinctive character" and that, on the other hand, "Blumer calls for the scientist to move beyond the empirical findings from a problematic investigation to some transcending theory or outside conceptual scheme." Put in simple form, these two sentences mean nothing more than that, on the one hand, I recognize that every empirical object has an individual uniqueness but that, on the other hand, it also possesses features that are common to a class of such individual objects. Thus, a scholar can describe and analyze an empirical object in terms of its distinctive makeup and career, and he can also describe and analyze it in terms of a theory that applies to a class of objects of which it is a member. I am unable to understand how McPhail and Rexroat can see "equivocation" in the fact that an empirical object may be perceived as distinct from every other empirical object and also may be perceived as sharing something in common with other empirical objects.

Some Further Observations on Alleged Methodological Differences.

I discern underneath the McPhail-Rexroat (1979:449–67) discussion what they really have in mind in alleging ontological and methodological differences between Mead and me. Their fundamental intention is to justify and promote a special mode of scientific inquiry that relies on controlled experiments or on observations closely akin to those made in controlled experiments. But they also regard themselves as followers of George Herbert Mead. They are, thus, forced to interpret Mead in such a way as to support their methodological orientation. They seek to do this in two ways. First, they try to interpret Mead's thought on "scientific method" in such a way as to uphold their methodological preference. Second, they endeavor to depict Mead's "social behaviorism" in such a manner as to fit their experimental or near-experimental commitment. I wish to comment on these two lines of their effort.

It is important to note that Mead did *not* see "scientific method" as a *special* kind of knowledge-producing procedure, or as a type of inquiry associated only with experimental science. To the contrary, he viewed scientific method as merely the extension of reflective intelligence. Referring to scientific method (1938:90), he said: "There is no difficulty in showing that, whether we call it the inductive or the experimental method, it is implicated in all intelligent conduct and that it has been involved in knowing the world at all times." Also,

> [t]he scientific character of the method is evidently found in the careful exactness with which the problem is defined, the data gathered, the hypothesis formulated, and the experiment carried out; but *these are merely the elaboration of the simple processes of everyday inference* by which we meet our constantly recurring difficulties. (Mead, 1938:83. My emphasis.)

With this modest view of the nature of scientific method, Mead could readily see scientific method in historical studies (p. 92) or speak of the "scientific treatment of religious institutions, beliefs, and experiences," or say that "more than one metaphysical problem [has been brought] into the range of scientific investigation" (p. 92), or declare that "The field of biblical dates is, of course, *one in which we find one of the most striking applications of scientific method* during the nineteenth century" (Mead, 1936:274–5. My emphasis).

Obviously for Mead, the mark of scientific method was the exercise of exacting care in (a) the setting of the problem, (b) the gathering of data, (c) the formulation of hypotheses or leading ideas, and (d) the testing of the ideas. Since these four steps can be executed in the case of naturalistic study, there is no difference at all between Mead and me. As I have said, there is nothing intrinsic in exploration and inspection to preclude the research scholar from specifying his problem exactly, from identifying his data carefully, from refining his leading ideas into clear form (formulating hypotheses), and from testing his ideas against the obdurate response of the empirical world (carrying out the experiment). McPhail and Rexroat have done nothing to show that it is impossible to carry out these four steps *with care* in the case of naturalistic study. Nor have they shown at all that it is impossible for the conscientious scholar who carries out these four steps to record the steps so that others may check on his experience. Indeed, naturalistic study in the form of exploration and inspection serves *the precise purpose* of enabling the research scholar to make a clearer identification of a problem, a more definite specification of what are the relevant data, a clearer formulation of leading ideas, and a more accurate identification of the obdurate empirical items that are to test the leading ideas. In direct opposition to what McPhail and Rexroat say, exploration and inspection lead the scholar to the empirical world in which the problem lies, instead of away from it.

To make sure that the understanding of these matters is fully clear, let me make some additional comments on the inaccurate renditions of Mead which McPhail and Rexroat (1979:449–67) make or imply repeatedly in their discussion.

> (1) The "exception" which Mead recognizes as the source of a scientific problem is in no sense confined to a challenge of an existing scientific law. It may be *any observation* which raises a new question, or sets a problem, or doesn't fit in with current thought or, as Mead says in one place, "the

observing of that which runs counter to accepted opinion" (Mead, 1936:284). In Mead's view, contrary to what McPhail and Rexroat imply, the "exception" which initiates scientific inquiry may arise from an exceedingly diverse background of antecedents. It may arise with the greatest of ease in the observation of the natural world.

(2) Mead stresses the need that the statement of the problem be made "in terms of the conditions of its possible solution." McPhail and Rexroat make a great deal of this statement, implying that it requires an exacting account of prospective research procedure, as in the design of a laboratory experiment. For Mead, the "conditions of its possible solution" had no such limitation; it referred to what was set by the problem and varied with the problem. Thus, Mead could recognize that careful historical studies that are used to establish biblical dates could be regarded as a striking application of scientific method. The term, "conditions of its possible solution," meant for Mead no more than an identification of the conditions that would allow for the careful execution of *whatever procedure* was needed to solve the problem; it did *not* mean adherence to a particular procedure.

(3) It is important to keep in mind that, although Mead used the term "experimental method" with great frequency, he recognized very clearly that it was not synonymous with "scientific method." He saw that "observation" outside of an experimental framework could be an integral and important part of scientific procedure. "There is just as much accurate technique in observation as there is in experimentation" (Mead, 1936:284). In no way did Mead exclude scientific observation from what I have spoken of as naturalistic study.

(4) It is important, also, to note that Mead saw that the part of the empirical world that is under scientific investigation has an *obdurate or resistant nature*. This obdurate nature is "there," in the "facts" which set the problem—and in the facts that have to be met by the proposed solution. They are the "hard data" of scientific study that have to be reckoned with. This obdurate or resistant nature of the empirical world that is under scientific study was not seen by Mead as eternal or immutable; it is recognized in true pragmatic spirit as subject to reconstruction. This is exactly my position.

To sum up, McPhail and Rexroat (1979:449–67) have grievously misrepresented Mead's ideas on scientific method in asserting that it cannot be employed in exploration and inspection. There are no fundamental differences between the ways in which Mead and I see methodology in scientific inquiry.

OBSERVATIONS ON MEAD'S "SOCIAL BEHAVIORISM"

As I have mentioned here, there is little doubt that McPhail and Rexroat are determined to depict Mead's thought in a way to make it fit their idea of how human group life is to be studied. Their idea has three compelling dimensions: It narrowly limits the scope of behavior that one is allowed to observe; it requires the investigator to be able to control or manipulate the behavior that is to be observed; and it requires the investigator to control and record his observations (McPhail and Rexroat, 1979:463). Mead's thought on the *nature of social behavior* is being squeezed by McPhail and Rexroat to fit this procrustean methodological bed—and, in the process, is being squeezed badly out of shape. We can see this deformation of Mead's thought by McPhail and Rexroat in what they propose in the latter section (pp. 460–6) of their article, "Investigating Mead's Ideas on His Own Terms." In that section, they present the two lines of study which, they say, represent the way in which Mead sees, and would study, "social behavior." These two lines of study are (1) the substitution of reflex movements in human behavior for the social meaning or character of that behavior, and (2) a reduction of social behavior to quantifiable units of overt responses. I wish to discuss each of these two lines of distortion of Mead's thought.

Substitution of Reflex Movements for Social Behavior

It is obvious from the discussion (see pp. 460–2 of their article) that McPhail and Rexroat regard the study of reflex movements to be the *major* way in which Mead would have us study human social behavior. They present three such studies of reflex movements (O'Toole and Dubin, 1968; Smith, 1971; and Cottrell, 1971) as exemplifying the investigation of Mead's social behavioral ideas "in terms of his own sociological perspective." I can say with unqualified confidence that Mead would have regarded as ludicrous the effort to center the scientific study of human social behavior in the reflex movements involved in such behavior. Viewed in terms of Mead's thought, such a shift to reflex movements suffers a serious disability: It replaces what is social in behavior by what is physiological. I wish to show this, using the cited O'Toole-Dubin study as a convenient illustration.

The O'Toole-Dubin study consisted of observing mothers who were spoon-feeding their infants and of counting the frequency with which each mother opened her mouth as she presented the spoon to the mouth of the infant. This study is hailed by McPhail and Rexroat as an exemplary study of Mead's ideas of what is involved in "taking the attitude of another." Yet, it doesn't even come close to catching what Mead saw as involved in taking the attitude of another. The spoon-feeding of the infant by a mother is what Mead spoke of as a "social act," one in which two organisms (the mother and infant) are adjusting their individual acts to one another in carrying out a joint act. In this instance, the mother would have the need of taking the "attitude of the infant," namely, to catch the perceived and the anticipated action of the infant so that the mother could adjust to the infant's action. The effort by the mother to catch the perceived and the anticipated action of the infant is a complicated matter—one that is dependent in large part on the kind of *social object* that the mother makes of the infant in the feeding act. Thus, the mother may see the infant in the feeding act in a variety of ways: as a good baby or an obstinate baby, as an infant who needs to be coaxed, as one who is making inordinant demands, as one who is delaying the mother's schedule to prepare dinner, as one who is to be nursed along with great care and attention, as one who is unwelcome but still has to be fed, and so on, in many different ways. These different ways in which the mothers may *see* their infants in the feeding act are definitely a "taking of the attitude" of the infant; they represent the ways in which the mothers see and treat the infants as acting toward them (the mothers). It is precisely these crucial objects—which mothers make of their infants in the feeding act—which are not revealed at all by the reflex movements. One would find out pitifully little about how a mother is taking the role of her infant by counting the frequency with which the mother opens her mouth as she extends a spoon to the infant's mouth. Such counting of her mouth openings will not tell us whether, as suggested, she sees the infant, at the time, as a burdensome demander, as a beloved object, as one who needs a great deal of guidance, as one who is possessed by a demon that needs to be exorcized, or as one who merely needs attention on schedule. The study of the mouth-opening reflex does not tell, at all, the kind of object that the mother is making of the infant. Yet, in Mead's thought, it is precisely this latter kind of knowledge that is essential to understanding the mother's *social* behavior toward the infant.

Mead saw the social behavior of human beings as constituted by their approaches and responses to one another as they engaged in their respective parts of their joint acts. These approaches and responses turn on how the human beings see and define each other in their interaction—the kind of objects they make of one another in the situations in which they are placed. Any scheme that proposes to study the social behavior of human beings, as seen by Mead, has to respect this social process. The study of the reflex movements of participants in the social process fails ignominiously to catch this social process. The study of reflex movements that are involved in social behavior may well fit McPhail and Rexroat's methodological procrustean bed, but such study grievously ignores what Mead saw *as central* to human social behavior.

Reduction of Social Behavior to Quantifiable Units of Overt Response

A similar verdict of distortion has to be made in the case of *the other form of study* which, McPhail and Rexroat declare, exemplifies Mead's ideas of social behavior. They (McPhail and Rexroat, 1979:462–5) speak of this second and remaining form of study as "exploratory-descriptive" research and illustrate its character by referring to a study by Melbin. McPhail and Rexroat propose their scheme of "exploratory-descriptive" research as a replacement for my scheme of "exploration" and "inspection"—a replacement which they announce as being faithful to Mead's idea of social behavior and, thus, as being a correction of my allegedly faulty rendition of Mead. Their scheme of exploratory-descriptive research is designed by them for naturalistic study—the study of the social life of human beings in their everyday natural settings. But McPhail and Rexroat find that their scheme of exploratory-descriptive research cannot be made to quite fit their *basic* methodological procrustean bed. So they make a concession by casting aside the requirement for the control and manipulation of the behavior that is under observation, and (p. 462) merely specify the other two requirements—limiting the scope of behavior to be observed, and having the investigator control and record his observations of his own behavior. However, within the framework of these two requirements, McPhail and Rexroat set up a *new* group of more exacting *requirements* that have to be met in order for social behavior in the natural world *to qualify* for study under their exploratory-descriptive scheme. From what they say—and particularly from the Melbin illustration—it seems clear that, to be studied in its naturalistic setting, social behavior must meet the following criteria:

> (1) The social behavior must be overt and thus open to direct observation;
> (2) the social behavior must be simple in makeup and brief in duration;
> (3) the social behavior must be capable of easy and unequivocal detection by investigators who are trained to make the same kind of observation; and
> (4) the social behavior must be capable of being counted in the form of clear-cut units.

This set of four requirements constitutes the *new procrustean bed* which human social behavior in natural life *has to fit* in order to qualify for study under the McPhail-Rexroat scheme of "exploratory-descriptive" research.

The question which has to be faced is whether human social behavior which is forced to fit this new procrustean bed represents social behavior as it was seen by Mead. My answer is resoundingly in the negative. To make this clear, let us consider each of the four requirements. The *first* requirement (that the behavior must be overt) rules out immediately the vast amount of covert behavior (the communication of the person with himself) which Mead elevated to such high importance in human group life. The *second* requirement (that the behavior be simple in makeup and have a brief span of duration) similarly rules out a vast portion of the complex and lengthy social acts that Mead recognized as taking place in natural group life. The *third* requirement (that the behavior be capable of easy and unequivocal detection by trained observers) puts to the side the sizeable amount of obscure and hidden behavior in natural life which can be identified only by a great deal of artful probing. Finally, the *fourth* requirement (that the behavior be capable of reduction to countable quantitative units) casts aside an enormous range and amount of social behavior that takes place in human group life. These simple observations show that human social behavior, as Mead recognized it to be in everyday life, has an abundance of important forms and developments which elude and, indeed, defy compression into the McPhail-Rexroat mold of their exploratory-descriptive research. Mead's ideas of social behavior definitely recognize the existence, in everyday life, of those social forms and processes which the McPhail-Rexroat scheme would exclude. Further, Mead never said, or hinted, that these forms and processes which McPhail and Rexroat would exclude cannot be studied scientifically.

I urge interested readers to examine carefully the two kinds of research which McPhail and Rexroat assert are the ways which Mead would have us use to study human behavior. These two kinds of research (the study of reflex movements and the highly compressed "exploratory-descriptive" research) fail overwhelmingly to catch what Mead had in mind in his conception of human social behavior. Mead did not have such a debased view of human social behavior as to equate it with reflex movements. Nor did he have such a constricted view of human social behavior as to confine it to small portions of simple, overt, quantifiable actions. Instead, Mead saw social behavior in its breadth, complexity, and natural character as it takes place in the multitude of *social acts* that make up the life of a human society. This was the empirical social world for Mead. Further, Mead's conception of scientific method fully permitted the application of scientific method to the naturalistic study of this empirical social world. In this naturalistic study, observations could be made, questions could be asked, problems could be narrowed and sharpened, data could be specified, leading ideas or hypotheses could be formulated, and special data could be selected to test the validity of the leading ideas. To contend or pretend that Mead's views did not allow for such direct scientific study of human social behavior in its natural empirical setting is to grievously distort Mead's views of both the nature of human social behavior and of the nature of scientific method.

To sum up, a careful examination of the McPhail-Rexroat (1979:449–67) article shows that they have seriously misrepresented (a) my ontological view of reality, (b) my view of naturalistic study, (c) Mead's view of scientific method, and (d) Mead's view of social behavior.

EX CATHEDRA BLUMER OR *EX LIBRIS* MEAD?*

CLARK MCPHAIL
University of Illinois

CYNTHIA REXROAT
University of Florida

American Sociological Review 1980, Vol. 45 (June:420–430)

Blumer (1980) hypothesizes we have misrepresented his views and those of Mead on scientific inquiry and social behavior, and that we have erroneously concluded their methodological perspectives diverge. Ironically, Blumer's paper exemplifies two of the fundamental problems we noted in his methodological perspective. First, he fails to specify the criterion in terms of which he makes the judgment of misrepresentation. Second, he fails to bring systematic evidence to bear on the claims of his hypothesis in relation to some criterion for judgment.

We proceeded differently. We indicated at the outset of our paper (McPhail and Rexroat, 1979:450, especially fn. 1, fn. 2, and fn. 3) that our criterion for judging convergence or divergence between Mead's and Blumer's methodological perspectives would be their written statements. When we attributed a position to Mead we provided citations to or quotations from Mead's statements documenting our claims. Blumer (1980) makes no less than 28 attributions of position, opinion or "thought" to Mead, yet offers documentation for less than one third of those attributions.[1] Instead, Blumer responds as he has in the past to those who offer non-Blumerian interpretations of Mead (e.g., Blumer, 1966; 1967; 1973; 1977: he simply asserts that *his* interpretation of Mead is *the* correct one! The availability of Mead's writings and edited lectures permit interested scholars to decide between a version of Mead *ex cathedra* Blumer or *ex libris* Mead.

In the following sections we examine Blumer's claims about his own ontological, methodological, and theoretical positions, as well as his claims about our misrepresentation. We examine his claims in terms of their internal consistency as well as the evidence from Mead's writings and from our (1979) paper. Our examination strengthens our initial judgment: Mead's and Blumer's methodological perspectives are divergent. Blumer's charges of misrepresentation are misdirected and reflect his own failure to examine what Mead has written and his failure to accurately report and respond to what we wrote.

ONTOLOGICAL DIFFERENCES

In his defense Blumer (1980:409–10 states his own ontological position and then, without citation or quotation, presents it as the ". . . basic tenets of Mead's pragmatism . . . ." We will not repeat our summary discussion of Mead's ontological position but invite readers to examine our synopsis (1979:457–9) or Mead's statements (e.g., [1900] 1964:8, [1903] 1964:54; [1917] 1964:196, 203; [1922] 1964:242; [1927] 1964:315–6, 318; 1932:275; 1934:78; 1936:275, 285; 1938:104–5, 275) and make their own comparison of his position with the one Blumer sets forth.

Blumer (1980) denies he is a "realist" or "Aristotelian essentialist" and proclaims allegiance to Mead's pragmatist position. The terms with which Blumer describes his naturalistic methodology make suspect his denial and his allegiance. On numerous occasions he refers to "the nature of naturalistic study" (p. 413), "the nature of scientific method" (pp. 415, 419), the "natural social world" (p. 412), "the *nature of social behavior* (pp. 416, 419) or "the natural character" of "social behavior" (p. 419). Webster's Third Edition defines "nature" as "the essential character or constitution of something, especially, the essence or

We thank Charles W. Tucker for commenting on a preliminary draft of this statement.

[1] None of Blumer's references to Mead's writings challenge any of the arguments presented in our paper, as our subsequent remarks will demonstrate.

ultimate form of something." If Blumer means something else by the terms "nature," "natural," or "naturalistic," he should provide us with a set of distinguishing criteria.[2] Otherwise we must conclude that Blumer either disagrees with or fails to understand Mead's (1936:275) contention that "science has gotten away from metaphysical dogmas as to what the nature of things is" and is concerned instead with "the ordering of events it observes."

The "ordering of events" is achieved through the responses—the behaviors—of the investigator and others. Blumer (1980: 410) protests he is not "designating the existence of an implanted, fixed and eternal reality," yet he makes repeated designations of the "nature" or "natural makeup" of human behavior. Such designations attribute the meaning or characteristics to the behavior rather than to the responses the investigator makes to the behavior. The meanings of a behavior are the responses made to it (Mead, [1900] 1964:8) and not the discovery or revelation of its "nature" or "natural makeup" at any one point in time or another.[3] The corroboration of the investigator's responses by another's response coestablishes the presence and meaning of that behavior. Such convergent responses (Mead [1927] 1964:315–6, 318) constitute the objective "stuff" with which science works. It is Blumer's failure to adopt this social behaviorist stance that makes his position so variable and confusing, if not contradictory. It is the same failure which separates Blumer from the pragmatist position with which Mead transcends the realist-idealist gap.

METHODOLOGICAL DIFFERENCES

Antecedents and Initiation of Inquiry. Blumer (1980:411) denies our (1979:451) charge that he presents an "erratic" characterization and analysis of the role of antecedent theory. To support his denial Blumer (1980:411) selectively quotes the first and final phrases, italicized below, from our discussion of his positions. He (1980:411) then writes he is unable to understand how those phrases establish his erratic position. They don't! The excluded phrases do. We wrote (1979:451):

> *On the one hand he is less sanguine than Mead with the adequacy of existing behavioral scientific theories, laws and beliefs.* Extant theories cannot provide benchmarks when the majority of theoretical concepts are too vague and ill-defined to be used in scientific inquiry (Blumer [1954] 1969:138). Blumer says these concepts, at best, may serve as "sensitizing concepts" in a preliminary exploration of the empirical world. This may result in the development of more "definitive concepts." Yet, on the other hand, Blumer ([1940] 1969: 181) warns of the ". . . risk and danger that the [theoretical] concept may coerce judgment and determine what is seen." He (1969:41) *warns investigators to beware "imprisonment" by their antecedent theoretical schemes."*

On the one hand, Blumer ([1940] 1969:181) says theory is so powerful it may coerce judgment, determine what is seen and, thereby, imprison the investigator. On the other hand, he ([1954] 1969:138) says extant theory is inadequate, too vague and ill-defined, to direct scientific inquiry. This is one basis for our judgment that he is erratic on this point. Further, because we understand the term "sanguine" to be defined as "optimistic" or "confident," we judge that Blumer is less sanguine than Mead ([1917] 1964:207; 1938:56) about extant theory as a source of hypothetical solutions to whatever area of activity or experience becomes problematic (Mead, 1936:264–5).

We also conclude Blumer is less confident than we are about applying Mead's methodological perspective to the study of human social behavior. Blumer (1980:416–9) contrasts the physiological movements of human beings with the "natural character" of their social behavior. His discussion of that contrast suggests a distinction Mead refused to draw—namely, that there is some essential characteristic or generic feature of human social behavior which renders it immune to investigation by "the scientific method." Mead ([1906] 1964:61) recognized no fundamental distinction between the researches of the social and biological and physical sciences "in point of method":

---

[2] It does not suffice to define these concepts in terms of one another as Blumer does when he writes (1980:412): "By naturalistic study I mean the study of conduct and group life as these occur naturally in the everyday existence of people . . .".

[3] "Resistance" is not a useful defining characteristic of "the nature" of the empirical world because this turns attention away from the responses of human beings and toward "the nature" of that to which they respond. Some readers may pound their desks when they read these comments and thereby meet with resistance. But resistance varies with response and the use of an electric drill or a laser beam, as compared with a fist, will produce varied resistance from the desk.

> Each is approaching problems which must be solved, and to be solved must be presented in the form of carefully gathered data. For their solution hypotheses must be constructed and tested by means of experiment or observation. With the complexity of the phenomena, of course, the application of the scientific methods will vary. The processes of observation, for example, will vary enormously in the study of a historical problem in the ancient world, and the study of the problem of variation where the material is immediately at hand.

The study of varied and complex human social behaviors in an ongoing situation might require a specialized data collection and analysis technique (for example, film recording) but variation in techniques does not qualify or change "the scientific character of the method" (Mead, 1938:83) which is found "in the careful exactness with which the problem is defined, the data gathered, the hypothesis formulated and the experiment carried out. . . ."

Blumer argues, as we explicitly acknowledge (McPhail and Rexroat, 1979:453, fn. 9–10), that Mead did not limit the application of scientific inquiry to experimental manipulation. Scientific inquiry is the explicit and formal extension of intelligent problem solution to all areas of human inquiry (Mead, [1906] 1964:61; [1917] 1964; [1923] 1964:248–66; 1936). Blumer correctly, but incompletely, notes Mead's reference to the application of scientific method to the historical analysis of disputed biblical dating.[4] He conveniently overlooks Mead's (1938:35) favorable reference to experimental studies and his (1936:400) comments on the merits of observation versus introspective studies of human behavior. It is simply not true, as Blumer (1980:411, fn. 1) claims, that Mead failed to discuss procedures for the study of human behavior. Mead did not write a handbook of research procedures; but, then, neither did Blumer. Both wrote about "methodological principles" and it is our contention that Mead's comments are both more explicit and extensive than Blumer's.

Exploration and Inspection. We (1979:462–3) recognize that exploratory research is the imperative first step in becoming familiar with the phenomena to be explained. We are less sanguine about what Blumer (1980:412) calls "inspection": the "meticulous examination" of the analytical element by "careful, flexible scrutiny of the empirical instances covered by the analytical element."

First, Blumer fails to tell us what one does when one engages in "meticulous examination" or "careful, flexible scrutiny." We think it might involve, at minimum, the description of the phenomena to be explained. Mead (1936:283–4) says the investigator should produce descriptions of as many instances of the problem as possible and, thereby, increase the facts known about the problem. He (1936:350) discusses the use of vocal and nonvocal gestures to discriminate or point out objects and (1936:378–80) to direct conduct with respect to the objects established by such gestures. He (1936:406) emphasizes the detailed information which must be noted when reporting the exceptional event. In this way investigators' activities establish, specify, describe and corroborate the phenomena to be explained. Second, Blumer (1980:413) advocates inspection "with an eye to disengaging the generic nature" of analytic elements. This exemplifies the Aristotelian conception of observation Mead criticized ([1917] 1964:184) because of the value it places on ". . . the insight with which [the investigator] recognizes the nature of the object," analyzes that nature "into essential characters" and therefrom formulates the definition of the object.

---

[4] Mead mentions "biblical dating" as an example of scientific challenge to dogma. Bishop Ulster (c. 1654) calculated the creation of the universe at 4004 B.C. His claims were subsequently challenged in the 19th century. Mead (1936:274) observed that "if you set up a dogma of that sort, science will inevitably undertake to find a problem in it . . . will at once turn about and ask for a justification . . . will look up documents, ask what they are, where they come from, who wrote them, and pull the dogma all to pieces." We are in complete agreement with Blumer on this point: textual analysis can be used to pull extant dogma all to pieces!

Here, again, we confront the fundamental divergence between Blumer's and Mead's treatments of observation. Blumer properly calls for direct observation of the empirical world but he places the emphasis upon discovering or recognizing the "generic nature of analytic elements" through inspection of empirical instances of the analytic category. Thereby Blumer directs attention toward the nature of the phenomenon and away from Mead's ([1900] 1964:8) emphasis on the response to the phenomenon: "*the meaning of the object is derived entirely from our reaction upon it*" (emphasis supplied). The investigator's activities impose order by specifying what must occur before the investigator (and others) can judge that phenomena have occurred, or that one phenomenon is related to, follows from, or occasions another. This is what investigators must do (Mead, 1938:83) if they are to proceed with "careful exactness" to define their problem, gather their data, and submit their hypotheses to the test of observed facts.

Hypotheses. Blumer (1980:412–3) offers six refutations of our (1979) claim that his treatment of hypotheses differs from Mead. We respond in turn. First, Mead (1936:346–91) does use synonyms for the term hypothesis in the lecture to which Blumer refers. However, it is difficult for us to read what Mead has written on scientific inquiry and escape the conclusion that "hypothesis" is his preferred term. "Hypothesis" is the crucial instrument in scientific inquiry, "the escape from the exception" or "the tentative solution to the problem" which must be submitted to empirical test against observed facts.

Second, we juxtapose Mead's term "hypothesis" with Blumer's term "discovery" because the former is an activity advanced against the empirical world by the investigator, whereas the latter is, according to Blumer, something drawn from the nature or character of that world. Again, the Meadian emphasis is on the actions of the investigator whereas the Blumerian emphasis is upon the nature of the world.

Third, Blumer denies our (1979:455) suggestion that he advocates or practices "atheoretical induction." But note his reaction to our summaries of studies of "taking the attitude of other"; that is, the individual's reflexive response to its own gesture. Blumer is concerned with the substance of baby feeding whereas O'Toole-Dubin (1968) merely took that substantive setting as an opportunity to observe and record the behaviors for a central theoretical concept in Mead's (e.g., 1936:360–85) explanation of coordinated behavior.

Fourth, we did not suggest that Blumer (1969:28–31) categorically rejects what he calls "the four customary means" of scientific inquiry. We (1979:454) explicitly summarized the reasons Blumer offers for rejecting most research done in those ways. The fact remains that Blumer consistently finds fault with conventional methods of study which require investigators to put up criteria for and empirical evidence against the claims of their hypotheses. Mead (1936:284) says that investigators must "take the hypothesis that you have formed and see if it will fit with the facts which you have before you." Blumer consistently resists, equivocates, or circumvents this challenge.

For example, Blumer claims we fail to catch the point of his discussion of testing hypotheses. He (1969:29–30) denies the ". . . value of testing hypotheses as the means of establishing the validity of premises when the premises themselves have not been empirically tested." We take it that Blumer is not using the term "premise" as synonymous with the term "assumption" (and, hence, something which is not subject to empirical check) but, rather, is using "premise" to refer to a basic proposition in a theoretical argument. By what process would such a proposition come to receive the empirical test to which Blumer refers? Mead (1936:285) says that one starts with a hypothesis which proposes a solution to one's problem, or an answer to one's question, and then submits that hypothesis to test. "You test it. When you have tested it, it becomes a working hypothesis. And if others test it and it works, it becomes a working theory." Of course, that theoretical premise (or proposition or universal) holds only so long as it is consistent with the last available set of observations. But to claim, as Blumer does, that one should not test hypotheses unless they are derived from empirically validated premises, is to deny the process by which empirically validated premises are constructed.

Fifth, we concede that Blumer's investigator might have problems or interests to guide initial exploration and inspection. However, if those problems or ideas are not explicitly stated "up front," we do not know the criteria in terms of which investigators judge that this or that phenomenon occurs. We are prevented from knowing whether "the guiding idea" was a useful one or was abandoned en route. If it was not useful, that should be reported, and, if it was useful, we need the criteria as instructions for our own exploration of the same phenomenon or for corroboration of the initial investigator's report. Finally, when investigators fail to give attention to and describe their own actions toward the phenomenon in question, they are more likely to conclude, mistakenly, that they have "discovered the nature of something" whereas, in fact, it has been established by their actions.

Sixth, we are not persuaded that Blumer's methodology permits the investigator to specify what was observed such that others can corroborate the initial report. It is clear that Blumer does not require such specification and corroboration. In response to our challenge, Blumer claims that, like Mead, "he too" considers these important matters. But, like Mead (1936:400), we think we are on much safer grounds "to come back to the conduct of the individual if you are going to [make judgments about his position] than to come back to something he reports to you by means of introspection." As we (1979:452, fn. 6) noted earlier, Blumer is neither unaware of the issues of specification and corroboration nor is he unaware of crude procedures with which they could be addressed. But his writings from 1928 through 1979 have given these matters such scant attention, or have discussed them in such obscure locations, that we can only conclude he has considered them unimportant until now.

Consequences of Scientific Inquiry. Blumer (1980) responds consistently to our charges of equivocation on the theoretical antecedents and consequences of scientific inquiry. He consistently omits the substantive illustrations of our contentions and then claims bewilderment when we find him erratic. On the present point, Blumer does concede that objects can be construed as distinctive or unique as well as being construed as members of a general theoretical category sharing common features. But his position still falls far short of Mead's (1936:285) explicit discussion of the process of formulating and empirically generating theoretical universals. Blumer's (1980:414) protest notwithstanding, this point is a clear example of an important difference between the ways Mead and Blumer view the use of hypotheses in scientific inquiry.

FURTHER METHODOLOGICAL DIFFERENCES

Blumer (1980:414–5) claims that our concern with promoting a special mode of scientific inquiry has led us to misconstrue Mead's methodological and theoretical perspective to serve our purpose. How does Blumer know what we "really have in mind" (cf. Mead, 1936:404)? Our initial concerns were with the social organization of individual behavior and experience, with the coordination of the ongoing behaviors of two or more persons into social acts, and with the import of vocal and nonvocal gestures for the organization of individual and social acts. Reading what Mead had to say about those matters led us to read what he had to say about the conduct of scientific inquiry. We were surprised—given his advance billing by Blumer (1969:1)—to find that Mead had so much to say! Thus, if it is possible for anyone accurately to reconstruct their intentions, we would judge that our substantive and theoretical interests led to an examination of Mead's methodological perspective. This is not quite what Blumer has discerned.

Blumer claims that we wish to restrict Mead's characterization and analysis of scientific inquiry to "controlled experiments." To the contrary, we wrote (1979:453): "Mead's analysis of scientific inquiry discusses the examination of hypotheses by means of experimental *and* nonexperimental observations *as well as* with thought experiments" (emphasis supplied). We further wrote (p. 462): "Not every problematic behavior, nor every phase of any problematic behavior, lends itself to experimental investigation." We also noted that Mead (1938:82–3) construed the experimental method as a set of requirements for generating knowledge and not as a data generation technique, and that he recognized that experimental tests of hypotheses were not always practical or possible. We suspect Mead favors experimental method because it involves the investigator's active intervention and manipulation of the world in the solution of problems, whether these involve specific but abstract categories of behavior in the laboratory (1938:35) or larger configurations of behavior in the ongoing life of the community ([1899; 1923; 1929] 1964).

Blumer (1980:415) persists in the claim that we "have done nothing to show that it is impossible to carry out [Mead's (1938:83) criteria for scientific inquiry] in the case of naturalistic study." As we have noted, Blumer *does not require* exacting care in the definition of the problem, the gathering of the data, the formulation or the test of the hypothesis. Blumer merely says his methodology does not prevent, or that it allows, meeting those criteria. We contend it is not sufficient (cf. Mead [1917] 1964:196–7) to leave these matters to the discretion of Blumer's (1980:415) "conscientious scholar."

If Mead's criteria for scientific inquiry can be employed in exploration and inspection, why aren't they? What happens if Mead's criteria are explicitly incorporated into Blumer's naturalistic methodology? If that incorporation alters Blumer's methodology then his perspective and that of Mead are obviously different.[5] If that incorporation does not alter Blumer's methodology, then he was ill-informed when he set out to develop his approach (1969:1) to deal ". . . explicitly with many crucial matters that were only implicit in the thought of Mead."

Blumer (1980:415–6) charges us with a series of "inaccurate renditions of Mead." These charges are without merit or foundation. First, contrary to Blumer's claims, we do not repeatedly assert or imply that the sole source of a scientific problem is an exception to an existing law. We wrote (1979:451) that the problem might involve "an exception to or breakdown of a theory, law, hypothesis, unit of analysis, equation, or some piece of equipment." We also noted (p. 451) "extraordinary events" as well as exceptions to "a law, theory, or belief." We recognize, now as then, that no area or phase of activity or experience is immune to such exception.

Second, Blumer (1980:416) takes exception to our (1979:451–2) discussion of stating "the problem in terms of the conditions of its possible solution." We do not, as he claims, require "an exacting account of prospective research procedure, as in the design of a laboratory experiment." To the contrary, the bulk of our discussion deals with the importance of producing descriptions of the problem to increase one's familiarity with those problematic features with which a hypothesis must deal (cf. Mead, 1936:283–4). Our discussion emphasizes description of the phenomena to be explained and thus parallels what Blumer calls the "exploration" stage of his own methodological approach.

Third, we stated in our paper (1979: 453–4)—and repeat here, as we noted above—our recognition that Mead did not equate scientific and experimental method. He certainly did not demean the importance of nonexperimental observation. Thus, Blumer's (1980:416) quotation of Mead, italicized below, is correct, but incomplete. Mead (1936:283) wrote:

> *There is just as much accurate technique in observation as there is in experimentation.*

---

[5] One inevitable alteration would be to eliminate Blumer's designation "naturalistic" which is antithetical to Mead's ontological and epistemological position (cf. Mead, 1936:275).

> What the experiment does is to take the hypothesis you have formed and see if it will fit with the facts which you have before you and other facts which you can gather.

Fourth, we are still uncertain where Blumer stands on the ontological issue. He writes about "this obdurate or resistant nature of the empirical world that is . . . not . . . immutable" (1980:416). We agree with Mead (1938:275). Reality is a presupposition of all scientific inquiry. The manipulatory phase of the act meets a resistance which answers to the preceding perceptual phase of that act (1938:104–5). But resistance varies as a function of response (cf. fn. 3, herein).

BLUMER'S VIEW OF "THE NATURE OF SOCIAL BEHAVIOR"

The final section of Blumer's paper (1980) contends our methodological perspective squeezes Mead's thought on "the nature of social behavior" badly out of shape. Blumer erroneously states our methodological position and then offers *no* documentation for any of the statements about social behavior he attributes to Mead.

On Methodology. Blumer (1980:416–8) confuses our discussion of controlled observation of behavior with our discussion of controlling the behavior which is observed. We did not suggest that all observation research—let alone all scientific inquiry—must involve the investigator's manipulation or control of the behavior to be observed. Experiments are distinguished by the controlled observation and recording of the consequences of the investigator's manipulation of the limited behavior(s) under study (cf. our discussion, 1979:454). Obviously, not all phenomena lend themselves to experimental investigation.

What distinguishes systematic exploratory-descriptive research? It presumes that some phenomenon is problematic for the investigator. The initial statement of that problem is not discovered "in the nature" of the phenomenon but is stated in terms of the implicit or explicit theoretical language of the investigator. This statement is progressively narrowed and refined through the investigator's increased familiarity with the phenomenon. This may take weeks, months, or even years. (Melbin [1972:93], reports he spent most of two years trying to clarify the issues involved in describing interpersonal behavior.) It requires repeated observation, detailed notes or records, and the examination of both against the initial statement of the problem. Those activities enable the investigator to provide a more explicit specification of the problematic features of the phenomenon. That, in turn, permits the systematic collection of additional data with which to describe the now-specified phenomena to be explained. This progressive narrowing of the scope of the investigation, this recognition of the significance of the investigator's own activities in specifying the problem (and, therefore, the importance of controlling and reporting what he or she has done so that others may know and do the same) are conspicuously absent from Blumer's formulation. In contrast, we judge Melbin's (1972) study of everyday patient-aide interaction in mental hospitals to be an exemplary piece of systematic exploratory-descriptive research because of the attention it gives these issues.

On Social Behavior. Blumer's (1980:416–9) remarks on "social behavior" misrepresent what we (1979) wrote, bear little resemblance to Mead's discussion of the points at issue, and propose a research agenda which is grandiose and naive. First, we do not regard—nor did we suggest—that "reflex movements" (i.e., involuntary acts) are the "major way in which Mead would have us study human social behavior" (Blumer, 1980:416). We (McPhail and Rexroat, 1979:460) use the term "reflexive," not "reflex," to designate those responses an individual makes toward its own behaviors.

Second, we categorically reject the distinction Blumer (1980:417) attempts to draw between "physiological" *(sic)* behavior and social behavior. Mead ([1924–25] 1964:279; 1936:368–85) uses the term social act to refer to the cooperative or coordinated activities of two or more persons. What is coordinated? Physical movements and vocalizations are coordinated! This includes movements of the entire body (e.g., coordinated marching or dancing), movements of portions of the body (e.g., coordinated tactile manipulations), or vocal and nonvocal gestures (e.g., coordinated conversation). It is important to repeat (cf. McPhail and Rexroat, 1979:458, fn. 15) that, in the usage of his times, Mead ([1924–25] 1964:286–7) termed vocal and nonvocal gestures "attitudes" and defined them as "stages in the act as they appear to others, [including] expressions of countenance, positions of the body, changes in breathing rhythms, outward evidence of circulatory changes, and vocal sounds."

What is the source of coordination? Mead (1936:360–85) discussed innate physiological differentiation as the source of complex coordinated behavior among invertebrates. He sought an alternate source for the indefinitely more complex coordination of human behaviors. He sought an explanatory principle which would locate in the activities of each participant in the social act elements of the other's contribution to that act. Mead's (1936:377) principle of organization was the vocal or nonvocal gesture by which one individual can simultaneously indicate to another, and to itself, "the elements which are of importance in co-operative activity" (1936:378). This is accomplished if the gesture calls out similar responses from the other and from the individual, thereby getting into each participant's activities elements of the other's contribution to the social act.

Mead ([1927] 1964:312) called such gestures "significant symbols." These are created, taught, learned, used, and revised by those who participate in a common language community. With such gestures the individual can point out things and give directions to others. Mead ([1922] 1964:244–5) wrote:

> In giving directions, we give the direction to ourselves at the same time we give it to another. We assume also his attitude of response to our request, as an individual to whom the direction has the same signification in his conduct that it has to ourselves.

and, elsewhere (1936:377):

> Through the use of language, through the use of the significant symbol, then, the individual does take the attitude of others. . . . If, now, the individual calls out this attitude in others by a gesture, by a word which affects himself just as it affects others, then he will call out the same attitude in himself as others would. . . . This gives the principal method of organization which, as I have said, we can study from the standpoint of a behavioristic psychology.

This discussion should make clear to others, if not to Blumer, that Mead uses the term "attitude" to refer to observable nonvocal or vocal gestures (even "physical movements"). Mead uses "taking the attitude of the other" (hereafter, TAO) to refer to the individual's response to its own gesture toward another as other responds to that gesture, and, Mead suggests, this can be studied behaviorally.

Third, Blumer is simply wrong, then, when he (1980:417) asserts the O'Toole-Dubin (1968) study "doesn't even come close to catching what Mead saw as involved in taking the attitude of another." O'Toole and Dubin were concerned with the reflexive behaviors of TAO. Their studies, and those of Smith (1971) and Cottrell (1971), attempted to determine if it was possible to observe and record, systematically, "reflexive responses"—the individual's response to its own gesture toward another. It is true that they did not compare the responses of other with the individual's gesture or with the individual's response to its gesture toward other. They therefore examined but a portion of TAO and of the social act. But their studies unquestionably demonstrate it is possible to observe reflexive responses. They thereby substitute systematic inquiry for dogmatic conjecture about TAO. The O'Toole-Dubin and Smith studies unquestionably demonstrate that the individual's reflexive responses to its own "directions" to other correspond to what we could reasonably expect other's responses to be. And there is abundant experimental (e.g., Rigney, 1972; Milgram, 1973) and nonexperimental (e.g., Melbin, 1972) evidence that other will comply with the directions it receives!

Fourth, Blumer's (1980:417) criticism of the TAO studies illustrates another problem with the objectives and consequences of naturalistic methodology. The

O'Toole-Dubin study is berated for addressing but a limited set of questions about the mother's responses to her own gestures toward the infant. Blumer proposes an additional list of questions an investigator would have to answer to provide the "kind of knowledge . . . essential to understanding the mother's *social* behavior toward the infant" (1980: 417). By implication, any research which does not simultaneously address all those questions fails to provide the "essential knowledge" Blumer requires and is, therefore, without merit. Blumer's grandiose objectives for any one piece of research illustrate the error Mead ([1917] 1964:200) referred to as confusing the "scientific attitude of being ready to question anything with an attitude of being willing to question everything at once." An investigator must have some unquestioned and stable ground on which to stand while examining the limited number of phenomena which can be systematically observed at any one time (cf. Miller, 1956).

Faced with problematic complex phenomena, the investigator can flounder in many directions at once or can divide the phenomena into a number of separate and smaller problems for investigation. The TAO observations and experiments address one set of questions regarding the complex social act. Melbin's systematic field observations address another. Couch and his students (e.g., Miller et al., 1975) have addressed related questions. Many important aspects of the social act remain to be examined, but we now know more about the empirical merits of Mead's view than we could have known by attempting to answer a multitude of questions at once.

If such an approach has merit for the comparatively "simpler" social act, it becomes mandatory for the broader and more complex social phenomena to which Blumer alludes. Several years of field research on crowd behaviors lead to the judgment that they are very complex phenomena, requiring many separate research foci (McPhail, 1972): for example, the assembling process (McPhail and Miller, 1973); shifts between elementary forms of individual and collective behavior within assembled gatherings (e.g., McPhail and Pickens, 1975; McPhail, 1978); and the dispersing process (e.g., McPhail, 1969). The examination of individual and collective behavior within gatherings can be further divided into the task of describing the phenomena to be explained (e.g., Pickens's [1975] description of spectator behaviors, or Wohlstein and McPhail's [1979] description of processions, marches, and other forms of collective locomotion), and the task of testing explanations of those phenomena (e.g., McPhail and Wohlstein, 1979).

Blumer's (1980:418–9) closing criticisms suggest that everyday complex social forms and processes will not yield to systematic exploratory-descriptive research. We disagree. The exploratory stages of the crowd research project focused upon overt behaviors because they could be observed and recorded.[6] Theoretical criteria were developed with which to judge the presence and extent of the selected behaviors under examination. This enabled the investigators to train others to make similar judgments. Some of those behaviors were "simple in makeup and brief in duration." Others were so rapid or involved so many participants (e.g., spectator and demonstrator behaviors) that videotape (Pickens, 1975) and film (Smith et al., 1975; Wohlstein and McPhail, 1979; McPhail and Wohlstein, 1979) records were made to permit repeated review, examination, and coding of the behaviors. Other phenomena developed over such extended time periods and spatial areas that, for example, only the termination of assembling, or the origins of dispersing, could be observed. This required the systematic use of interviews, questionnaires, and written narratives to obtain participants' and observers' reports of their own and others' behaviors. Those records were subject to similar criteria for coding judgments noted above. In both cases this permitted quantitative treatment of those judgments. In short, one's characterization of complex social forms and processes, and the methodological recipe one follows, may facilitate their systematic investigation, or may place them beyond the pale of scientific inquiry.

---

[6] It should be noted that the "covert communications" to which Blumer refers cannot be observed until they are reported by people. The reports are overt behaviors and they can be treated accordingly.

CODA

Blumer has been a significant voice in the sociological wilderness of surveys and secondary analyses, urging serious students to observe and become familiar with the behaviors they seek to explain. There is no substitute for exploratory observations but they are not sufficient. Beyond making contact with the empirical world lies the challenge of what the investigator does, once contact is made. The specification and description of the problematic behaviors are not located in the nature of the empirical world but are functions of the investigator's response to that world. The theoretical hypotheses offered as resolutions of the problematic behaviors must be more than guiding ideas. They must be stated in such a way that they can be subjected to test against observed facts and, thereby, accepted, rejected, or revised.

MANUSCRIPTS FOR THE
ASA ROSE SOCIOLOGY SERIES

Manuscripts (100 to 300 typed pages) are solicited for publication in the *ASA Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Suzanne Keller, Department of Sociology, Princeton University, Princeton, NJ 08540.

EDUCATION AND FERTILITY: IMPLICATIONS FOR THE ROLES WOMEN OCCUPY*

American Sociological Review 1980, Vol. 45 (June:431–447)

The interplay between education and fertility has a significant influence on the roles women occupy, when in their life cycle they occupy these roles, and the length of time spent in these roles. The overall inverse relationship between education and fertility is well known; but little is known about the theoretical and empirical basis of this relationship. This paper explores the theoretical linkages between education and fertility and then examines the relationships between the two at three stages in the life cycle. It is found that the reciprocal relationship between education and age at first birth is dominated by the effect from education to age at first birth with only a trivial effect in the other direction. Once the process of childbearing has begun, education has essentially no direct effect on fertility; but it has a large indirect effect through age at first birth.

No factor has a greater impact on the roles women occupy than maternity. Whether a woman becomes a mother,[1] the age at which she does so, and the timing and number of her subsequent births set the conditions under which other roles are assumed. Some may deplore this situation and it may be changing, but the dominance of motherhood continues to be a fact for the vast majority of women. While there is clearly variance in this role dominance, the assumption of nonfamilial roles varies markedly with the fact, timing, and extent of maternity.

Education is another prime factor conditioning female roles. Education is expected to impart values, aspirations, and skills which encourage and facilitate nonfamilial roles. It is possible that better-educated women may assume less traditional role patterns than less-educated women with identical fertility histories. However, it is also likely that education affects women's roles through differing patterns of fertility. This paper discusses some of the possible linkages between education and fertility and reports analyses bearing on: (1) the relationship between education and age at first birth, (2) the effects of education on the timing of subsequent births, particularly on the experience of short birth intervals, and (3) educational differences in wanted family sizes.

EDUCATION–FERTILITY LINKAGES

Given the importance of the interplay between education and fertility for the roles women occupy in industrialized

This is a revised version of a paper presented at the annual meeting of the American Sociological Association, San Francisco, September, 1978.

This analysis was supported in part by grants from the Spencer Foundation to Ronald R. Rindfuss, from the University Research Council of the University of North Carolina to Ronald R. Rindfuss, from a subcontract to Ronald Rindfuss of NICHD grant No. 10751, from the Graduate School of the University of Wisconsin-Madison to Larry Bumpass, by a Center for Population Research grant No. 05798 to the Carolina Population Center from the Center for Population Research of the National Institute of Child Health and Human Development, and by a Center for Population Research grant No. 05876 to the Center for Demography and Ecology of the University of Wisconsin from the Center for Population Research of the National Institute of Child Health and Human Development. The authors gratefully acknowledge the able research assistance of Barb Witt and Cheryl Knobeloch, and the comments of two anonymous reviewers.

[1] Here, and throughout the paper, we use the term "mother" in its social rather than biological sense. The biological mother is the female who gives birth to the child. The social mother need not be the biological mother; but, typically, the two are the same. It is the social mother that has primary responsibility for the care and nurture of the child. This role need not be occupied by a female, but, typically, it is. Also, the word "children" throughout this paper is used in its social, rather than biological, sense.

societies, there has been surprisingly little attention paid to the causal linkages between the two.[2] In part, this may be because the possible causal connection between fertility and education is exceedingly complex. Some have assumed that education affects fertility (e.g., Westoff and Ryder, 1977; Rindfuss and Sweet, 1977; Cho et al., 1970; Whelpton et al., 1966), and some have argued that fertility also affects education (Waite and Moore, 1978).

Most of the theory and research concerned with education and fertility conceptualizes both in terms of their end products: completed education and children ever born. In fact, children come one at a time (usually), and education is completed a year at a time, sometimes a course at a time. Children can come close together, or at intervals of 10, 15 or even 20 years. Formal schooling can be completed without interruption; or it can be completed after short or long interruptions (Davis and Bumpass, 1976). Models of education and fertility should reflect the fact that education and fertility are processes which take time to complete and which can intercept each other in complex ways.

The overall relationship between education and fertility has its roots at some unspecified point in adolescence, or perhaps even earlier. At this point aspirations for educational attainment as a goal in itself and for adult roles that have implications for educational attainment first emerge. The desire for education as a measure of status and ability in academic work may encourage women to select occupational goals that require a high level of educational attainment. Conversely, particular occupational or role aspirations may set standards of education that must be achieved. The obverse is true for those with either low educational or occupational goals. Also, occupational and educational aspirations are affected by a number of prior factors, such as mother's education, father's education, family income, intellectual ability, prior educational experiences, race, and number of siblings (for example, see Hout and Morgan, 1975).

Occupational and educational aspirations are also reciprocally related to evolving fertility preferences. These fertility preferences include both number and timing preferences, that is, whether a first birth is wanted ever and, if so, when. The number and timing preferences may be related if, for example, a desire for many children leads to a desire to begin childbearing as soon as possible (Bumpass and Westoff, 1970). Moreover, the preference for postponing a first birth may lead to interests in other areas which may then lead to a decision not to have any children. There is evidence that repeated postponement of the first birth is a typical pattern among those who are voluntarily childless (Veevers, 1973). Such preferences for timing are necessarily vague, but nonetheless important. Some young women may wish to have a baby as soon as possible, perhaps to establish an adult identity separate from their parents, or to fulfill strong nurturing needs. Such aspirations among young women are likely to have a negative effect on evolving role and educational aspirations. Similarly, a young woman who is sure she does not want to have a child any time soon, if at all, may expand her role and educational aspirations accordingly. Influences in the opposite direction operate as the threat of early fertility to educational attainment are recognized and fertility desires are adjusted accordingly.

Both of these preference sets (occupational and educational aspirations as well as fertility preferences) influence actual age and education at first birth through a set of intervening variables[3] that include the standard intermediate variables affecting exposure to intercourse, conception risk and gestation and parturition (Davis and Blake, 1956; Bongaarts, 1978).

Adolescents with higher educational and occupational goals may choose social patterns that are less likely to lead to early marriage, that is, "not wanting to go steady or get serious with boys," because they want to go to college. They may be less willing to engage in intercourse because of the threat of possible pregnancy to their educational or career plans. Sexually active adolescents with high educational aspirations may be more likely to try to control the risk of pregnancy through careful contraceptive use.

---

[2] The work of Holsinger and Kasarda (1976) for developing countries is an exception.

[3] In actual practice, we know of no case where all the intermediate variables are adequately measured. Models are evaluated as if there were direct effects, with researchers unable to specify the precise nature of the social and economic effects on fertility as they operate through the intermediate variables.

Adolescent women who desire early motherhood (and presumably early marriage) are likely to follow social patterns that lead to early intensive emotional involvement; and, when sexually active, this group may have relatively low motivation to avoid pregnancy. Such patterns may lead indirectly to lower educational achievement because of an early age at first birth.

Early marriage may have a direct effect on reducing educational attainment,[4] for example, when a girl leaves school in order to be married. These social patterns also have an indirect effect on education through factors affecting pregnancy and early age at first birth.

It should be noted that in the reciprocal relationship between education and age at first birth, the effects of education on age at first birth can only be the result of the intermediate variables discussed above (also, see Davis and Blake, 1956; Bongaarts, 1978) whereas the effect of age at first birth on education may also include a direct effect.

Both age and education at first birth can affect subsequent role and educational aspirations, and subsequent preferences for the timing and number of children. These subsequent aspirations and preferences are also reciprocally related. After the birth of their first child some women may find that they wish to reduce their fertility goals, increase their occupational goals, and return to school. Others who had planned on continuing their education may decide to have more children, or to quickly become pregnant again, either because of great satisfaction in the mother role, or because of a sense that it is an all-consuming role that precludes other options, or because they are not sure of what else to do.

Education, age at first birth, the possibly revised occupational and educational aspirations, as well as timing and number preferences all affect various aspects of the intermediate variables in a process similar to that elaborated above with respect to the period before the first birth. The period prior to the first birth includes an unmarried and sexually inactive period as well as a married interval for most women. For most (but not all) women, the period following the first birth begins within marriage. Some women will not yet be married and others will have married and separated or divorced by the time of the first birth. At the second birth, a woman may be never married, currently married, widowed, divorced or separated (Rindfuss and Bumpass, 1977). Marital instability is an important social factor in the social patterns category in each segment to the extent that it affects other intermediate variables such as frequency of intercourse, periods of abstinence, and use of contraceptives.

Fecundity is largely exogenous to the processes we are examining, though it has a clear effect on the timing of the first birth and may mediate the effect of age at first birth on subsequent fertility.

While these potential intersections in the relationship between education and fertility warrant more intensive study, that is not our purpose in this paper. The point we are attempting to make in the preceding discussion is that the observed relationship between completed education and completed family size is the cumulative outcome of a complex process that involves attitudes and decisions about both education and fertility that may change as time passes or as the woman moves from one stage to the next, and that it is necessary to examine empirically the various stages in the process.

Data

The data used are from the 1970 National Fertility Study (NFS), a multipurpose study based on a national probability sample of 6,752 ever married women under 45 years of age residing in the continental United States (Westoff and Ryder, 1977). Complete birth and pregnancy histories were obtained, thus permitting analysis of age at first birth and of birth intervals. Unfortunately, a complete educational history was not obtained. Only education at interview and education at marriage were obtained. This means that we have to use education at marriage as a proxy for education at first birth. For most women this is a reasonable proxy, since the correlation between age at first birth and age at first marriage is 0.74. In order to check the reasonableness of using education at marriage, we reran all the analyses using education at interview, and results were unaffected. However, it should be recognized that for younger mothers the first birth is likely to precede the first marriage. Finally, it should be noted that there were no questions asked about educational or occupational aspirations during the adolescent and young adult years.

---

[4] Note, however, that Voss (1977) finds a negative effect of age at first marriage on educational attainment. Marini (1978) argues, and we agree, that this finding of Voss is the result of the lack of an adequate instrument for age at first marriage.

Although not reported in detail here, wherever possible we have also examined data from the 1973 National Survey of Family Growth (FGS) (NCHS, 1978) (a national probability sample of 9,797 women under age 45 who had ever been married or who were never married mothers in 1973), and essentially comparable results were found in both data sets.

Education and Age at First Birth

In the absence of accurate data on the intermediate variables, the relationship between the fertility and educational processes can be conceptualized as a simple causal process. The aspirations, plans, and decisions (and "apparent" nondecisions) leading to an early first birth may result in lowered educational aspirations and achievement. Women who desire and obtain a high level of education may adjust their fertility preferences accordingly. Both the educational and the first birth process are affected by a set of exogenous factors reflecting background characteristics and characteristics of early adolescence. A model of these relationships is shown in Figure 1. The rationale for this set of exogenous variables, and their effects on education and age at first birth, is considered elsewhere (Rindfuss and St. John, 1979); in the present paper we concentrate only on the relationship between education and age at first birth. Table 1 indicates the measurement of these exogenous variables, and the Appendix reports the zero-order correlations among all the variables in Figure 1.

That the relationship between education and age at first birth should be viewed as potentially reciprocal is often overlooked: one direction of causation is usually emphasized to the exclusion of the other. For example, Jaffe (1977:22) asserts: "Pregnancy is the most common cause of school dropout among adolescent girls in the U.S." Others, however, contend that education determines age at first birth; and, further, that women who get pregnant while still in school do so to have an "acceptable" reason for dropping out of school (Cutright, 1973). Since there is considerable overlap in the time when women leave school and the time when they have their first child (median age at first birth is currently about 22, and, of recent cohorts, 25% have their first birth by the end of the 19th year), it is important to investigate the extent to which the educational attainment process and age at first birth process are reciprocally related.

The part of the model shown in Figure 1 of direct interest here is the relationship between education and age at first birth. We allow for a reciprocal relationship between these two variables, with each affected by other variables in the model as well. Age at first birth is computed from the date of respondent's birth and date of birth of respondent's first child. Education, as noted, is education at marriage, not education at first birth. In order to estimate the reciprocal relationships between education and age at first birth, instrumental variables are needed for each of the two endogenous variables—that is, variables are needed which directly affect one of the endogenous variables but not the other, which are not causally determined by the endogenous variables, and which are not correlated with the unspecified source of the endogenous vari-

Figure 1. A Model of the Relationship between Educational Attainment and the Beginning of Motherhood

Table 1. Measurement of Variables in the Education and Age at First Birth Model

Variable Label	Variable Name	Units of Measurement	Description	Mean	Standard Deviation
DADDSOCC	Respondent's father's occupation	Duncan's SEI scores	Missing data were given the mean value	30.209	21.370
RACE	Race of respondent	Dummy variable	Blacks are coded 1, all others coded 0	0.099	0.299
NOSIB	Respondent's number of siblings	Actual number is coded		3.889	3.035
FARMBACK	Respondent's farm background	Dummy variable	Coded 1 if respondent grew up on a farm, all others coded 0	0.330	0.470
REGNBACK	Region where respondent grew up	Dummy variable	Coded 1 if respondent grew up in South, all others coded 0	0.357	0.479
ADOLFAM	Household composition when respondent was 14	Dummy variable	Coded 1 if respondent lived with 0 or 1 of her parents at age 14, coded 0 if she lived with both parents at age 14	0.183	0.387
RELIGION	Respondent's religious preferences when growing up	Dummy variable	Coded 1 if Catholic, all others coded 0	0.231	0.421
YOUNGCIG	Whether respondent smoked at a young age	Dummy variable	Coded 1 if respondent smoked before age 16, coded 0 otherwise	0.136	0.342
FECUND	Whether respondent had a miscarriage before the first birth	Dummy variable	Coded 1 if respondent had a miscarriage before the first birth; coded 0 otherwise	0.099	0.298
ED	Respondent's education	Years of schooling completed	This is education at first marriage	11.595	2.360
AGEFST	Respondent's age at first birth	Years		22.012	4.079

Note: Throughout, the usual practice of deleting missing data cases is followed.

able for which it is not an instrument (Duncan, 1975; Heise, 1975). As can be seen from Figure 1, fecundity is used as the instrument for age at first birth and respondent's father's occupation as the instrument for education. Fecundity is measured by whether or not the respondent had a miscarriage prior to her first birth.[5] A miscarriage before the first birth postpones the first birth in a direct and obvious way: it takes time to conceive again and carry that conception to successful parturition. It also gives the woman a second chance if she wants to contracept. The additional time involved as the result of a miscarriage before the first birth can be substantial since approximately one-fourth of the women who have one miscarriage before their first birth have two or more miscarriages before their first birth.

A miscarriage before the first birth should have no effect on education, except indirectly through age at first birth. This would occur only if the woman dropped out or was expelled from school prior to the miscarriage because of the pregnancy. If this were the case, then the miscarriage would be correlated with the disturbances in the education equation and would be unsuitable as an instrument. However, this is unlikely because the vast majority of miscarriages occur in the early months of a pregnancy, before it is obvious to observers that the woman is pregnant, and often before the woman knows that she is pregnant (see National Center for Health Statistics, 1966). If the woman is unmarried, she is unlikely to notify the school that she is pregnant until it becomes absolutely necessary. It is probably in part for this reason that unmarried women often do not seek prenatal care until very late in pregnancy (National Academy of Sciences, 1973). Furthermore, education should not have any effect on whether or not there is a miscarriage before the first birth. The only exception to this statement would involve a woman obtaining an induced abortion in order to complete her education. However, induced abortions are so grossly underreported in United States fertility surveys that reported miscarriages are essentially spontaneous miscarriages.

That respondent's father's occupation affects respondent's educational attainment is well known (Alexander and Eckland, 1974; Blau and Duncan, 1967; Kerckhoff and Campbell, 1977; Sewell and Hauser, 1977) and does not require further elaboration here. We also argue that father's occupation does not have a direct relationship with age at first birth. Rather, we would argue that the relationship is indirect through education. It can be expected that families of an orientation in which the father has a high status job would be more likely to encourage daughters to postpone the first birth than families of an orientation in which the father has a low status job. However, the most likely explicit and implicit justification for this encouragement would be to allow daughters time to complete their education, and thus the effect on age at first birth would be indirect. However, there may also be an intergenerational transmission of norms regarding age at first birth. (Leonetti [1978] provides a good example of this in the case of Japanese-Americans.) To the extent that socioeconomic status directly affects the intergenerational transmission of norms regarding age at first birth—that is, in addition to the indirect transmission through educational aspirations—then respondent's father's occupation would not be a suitable instrument for education. Recent work by Thornton (forthcoming) suggests that there is no direct transmission of fertility norms from parental status. Instead, this influence was transmitted through the education of the offspring.

---

[5] There is some evidence that a history of miscarriage greatly increases the chance that subsequent conceptions will be terminated by a miscarriage (Funderburk et al., 1976; Shapiro et al., 1971). Given the unreliability with which fetal losses are reported in pregnancy histories (Bumpass and Westoff, 1970) and given the fact that very early miscarriages are often unnoticed by the woman, we experimented with alternative and more complex measures of fecundity which incorporated information from the woman's history subsequent to the first birth. However, the simple measure of whether or not the woman had a miscarriage prior to the first birth proved to be the strongest predictor of age at first birth, and this is the measure that has been used in the final models.

In order to examine our assumption that parental socioeconomic status does not have a direct effect on the transmission of norms regarding age at first birth, we examined the determinants of ideal age at first birth. The 1970 NFS included the following question:

"Q. 3: What do you think is the ideal age for a woman to have her *first* child?"

Although this question suffers from all the problems of "ideal" questions (Blake, 1966; Bumpass and Westoff, 1970; Rindfuss, 1974; Ryder and Westoff, 1969) as well as some problems specific to this question (Rindfuss and Bumpass, 1978), it does provide the best measure available for norms regarding age at first birth. Using a sample of recently married women in order to minimize the possibility that the responses to the question would be affected by the cumulative maternal experience of the woman, we find that, after other appropriate factors are controlled, father's occupation has no significant direct effect on the ideal age to have a first birth. This further supports Thornton's results and supports the theoretical argument that parental socioeconomic status influences age at first birth only indirectly through its effect on the offspring's educational aspirations, and thus supports the use of father's occupation as an instrument for education in our model.

However, somewhat less consistent support was found in an examination of the 1971 National Survey of Young Women data. Since father's occupation was not available, the relationship between father's education and ideal age at first birth was considered for this sample of teenagers 15–19 years of age. While most of the association is accounted for by educational aspirations, ideal age at first birth is 0.4 years lower among the children of high school graduates than among those of fathers who attended college, net of other factors. While this modest net effect of father's education cautions our theoretical position, we would expect the net effect of father's occupation on ideal age at first birth to be considerably weaker.

Before presenting the results, it is necessary to discuss some of the variables which are not included in Figure 1 and the possible biases their exclusion might introduce. The first is marriage. Although we recognized the role of age at marriage in the earlier discussion in this paper (especially since it is incorporated in sexual experience), it is age at first birth that is emphasized both there and in our analysis here. Clearly, age at first marriage and age at first birth are closely related, normatively and empirically. However, we feel that the first birth has greater consequences for the life style and roles of the woman (Rindfuss, 1979), and that the effects of the first birth are more permanent than those of first marriage. Marini (1978) has recently argued that age at marriage is more important than age at first birth in the transition to adulthood because age at marriage "usually sets a lower limit on the age at which first birth occurs." We disagree for the following reasons: In the first place, motherhood frequently precedes first marriage. (And this is more likely to be the case the younger the age at first birth.) Second, some people may initiate the serious consideration of marriage on the basis of when they want to begin parenthood, as reflected in the phrase "time to settle down and start a family." The high incidence of premarital intercourse argues against the notion that age at first marriage sets a lower bound on exposure to the risk of conception. Third, "becoming a parent" is the modal response of married parents to the question of what marks the transition to adulthood (Hoffman, 1978). Fourth, parenthood is more permanent than marriage, particularly for women since children tend to stay with the mother following a marital disruption. Preston (1975) has estimated that almost half of the current marriages will end in divorce; thus, women often move in and out of the wife role. Finally, and perhaps most importantly, motherhood roles more severely constrain other life options of a woman than do marital roles, especially during the early childbearing years. For these reasons, our emphasis is on age at first birth. Given the high correlation between age at first birth and age at first marriage, and given that both are affected by similar exogenous variables, we have not included both in the analysis. Furthermore, given the assumptions of the model, the exclusion of age at first marriage will not bias our estimates of the relative importance of the processes leading to educational attainment and to the first birth.

In order to allow women sufficient time to get married (and, thus, be eligible to be in the sample) and to have a first birth, the analysis of the education-age at first birth relationship will be limited to women aged 35–44. Most of those who will ever marry before the end of the reproductive period are married by age 35. For example, the proportion of women ever married increases from 0.873 at ages 25–29 to 0.926 at ages 30–34 to 0.941 at ages 35–39. But the proportion of women ever married increases only slightly to 0.946 at ages 40–44 (U.S. Bureau of the Census, 1972). The same holds true for first births. Most of those who will ever give birth do so by age 35. For example, 79.2% of the birth cohort of 1930–1934 had a live birth by ages 25–29, 87.7% did so by ages 30–34, and 90.2% had a live birth by ages 35–39. This percentage increased only slightly to 90.8% by ages 40–44. Less than 3% of the women in this birth cohort who had a live birth had it after age 35 (Heuser, 1976).

Childless women are excluded from this analysis at age at first birth. Only a small proportion (less than 10%) of the married women in these cohorts remained childless (Heuser, 1976). To the extent that postponement leads to voluntary childlessness (Veevers, 1973), this exclusion could lead to a weaker estimated effect of age at first birth than actually exists. However, childlessness in these cohorts was primarily a product of fecundity impairments.

The model shown in Figure 1 includes background characteristics, aspects of early adolescence, and the reciprocal relationship between education and age at first birth. Period factors are not included, and this needs to be kept in mind when interpreting our results. The respondents in this analysis were aged 35–44 in 1970. Taking 15 as the youngest age at first birth and 35 as the oldest means that these women were having their first births from 1941 to 1970. During this long period, there were a number of events affecting the timing of fertility, including World War II, the Korean War, and the Vietnam War. Those women who postponed their first birth were, of course, exposed to more of these period factors, which could affect the timing of their first birth. Since so little is known about the nature of period factors that affect the timing of fertility (Rindfuss et al., 1978), they cannot be explicitly included in the analysis. Furthermore, the younger women in our sample experienced the period factors at different ages than the older women in the sample. To see if this would affect our results, we ran the model separately for women aged 35–39 and 40–44. The results were virtually identical for the two groups.

The work of Easterlin (1962; 1966 and 1973) and others suggests that the financial status of the respondent's family of orientation while the respondent was an adolescent will affect the age at which she has her first child. Unfortunately, we do not have a direct measure of the respondent's parents' financial status while the respondent was an adolescent. However, a number of background variables in the model, such as race, number of siblings, farm background, regional background, and family composition when respondent was 14, indirectly control for the respondent's family's financial situation.

Further, the model shown in Figure 1 also does not include the labor force experiences of women. As noted earlier, labor force experiences and aspirations are likely to affect, and be affected by, childbearing and childbearing preferences. In fact, there is a long literature on this relationship (see Waite and Stolzenberg, 1976; and Smith-Lovin and Tickamyer, 1978, for recent summaries of this literature). Unfortunately, adequate labor force participation information is not available.

Estimation of the effects shown in Figure 1 was accomplished by using two-stage least squares regression analysis (Goldberger, 1964; Johnston, 1972). The estimates were made using ordinary least squares in two steps, making the appropriate corrections as outlined by Hout (1977). The results are shown in Table 2.

Table 2. Metric and Standardized Coefficients Measuring the Reciprocal Relationship between Education and Age at First Birth, 1970 NFS[a]

Independent Variable	Dependent Variable	Metric Coefficient	Standardized Coefficient
Education	Age at First Birth	0.741*	0.429*
Age at First Birth	Education	0.075	0.130
	Correlation of Disturbances (U and V): −0.255		

[a] N = 1,766.

* Significant at 0.05.

This table shows only the results for the endogenous variables; results for the complete model are reported and discussed elsewhere (Rindfuss and St. John, 1979).

The effect of education on age at first birth is significant—both statistically and substantively. Each additional year of schooling results in the delay of the first birth by approximately three-quarters of a year. However, the effect of age at first birth on education is not statistically significant; and even if it were, the effect would be trivial substantively.

The results shown in Table 2 are based on the assumption of linear effects. It might be argued that the effect of age at first birth on education is not linear. The inclination to have a birth at a very young age may have more serious effects on educational plans than the preference to have a child at a later age. The potential conflict between school and motherhood is greatest at the younger ages at first birth. This suggests that a nonlinear age at first birth effect on education should be specified. Such a specification should force a difference of a year at the younger ages at first birth to be larger than a difference of a year at the older ages at first birth. We used three different transformations of age at first birth (AGEFST) to explore this possibility: (1) LN (AGEFST), (2) 1/AGEFST, and (3) $1/(\mathrm{AGEFST})^2$. The model shown in Figure 1 was reestimated for each of these three transformations. In each case the results are the same as the linear model: age at first birth does not have a significant effect on educational attainment.

Furthermore, there is some evidence to suggest that the family building process may be different for whites and blacks. For example, blacks have higher illegitimacy rates than whites (NCHS, 1977), and blacks appear to rely more heavily on relatives to take temporary, but primary, care of children born to young mothers than whites (Rindfuss, 1977). In order to check for a potential interaction with race, we reran the analysis separately for whites and blacks.[6] The important point for the present analysis is that, for both blacks and whites, education has a strong and significant effect on age at first birth, but age at first birth has an insignificant effect on education. Thus, our results are unaffected by any racial interaction.

In the relationship between education and age at first birth, the principal direction of causality is from education to age at first birth. Those who have recently examined the relationship between education and age at first marriage have found corroborating results (Marini, 1978; Alexander and Eckland, 1978), namely, that education has a much stronger effect on age at first marriage than age at first marriage has on education. Given the sheer amount of time the mother role requires in contrast to the wife role, the timing of the first birth has greater consequences for the roles women occupy. Yet, it is interesting to note that (ignoring the differences between the samples used here and those used by Marini [1978] and Alexander and Eckland [1978]), age at first marriage appears to have a somewhat greater effect on education than age at first birth. Even though age at first birth has a greater effect on the roles occupied by women, age at first marriage could have a stronger effect on educational attainment because first marriage schedules are younger and more compact than first birth schedules. Thus, more marriages take place during the years in which women are in school.

---

[6] Other nonwhites were not included.

The finding that age at first birth has only a very small effect on educational attainment may seem paradoxical, given the social policy concern with the pregnant girls who have to drop out of school and face reduced social opportunities as a consequence. Such a fate is unquestionably experienced by some women, particularly those among the 3% to 6% of the American cohort that have had a first birth before age 17. But the fact is that the vast majority of women do not get pregnant while they are enrolled in school. Even among those who do become mothers at ages at which society expects one to be in school, the direction of causality might run from education to fertility. Zelnik and Kantner (1978) and Ross (1978) suggest that a significant minority of premarital pregnancies were intentional. To further explore this issue, we compared the age at leaving school[7] with age at first birth for women who become mothers at age 17 or younger. If leaving school and the first birth occur in the same year, it is ambiguous which process dominates. But for those who left school more than a year before their first birth, one can assume that the educational process is affecting the fertility process. Surprisingly, more than 40% of the women who had a first birth at age 17 or less dropped out of school at least a year prior to becoming a mother—which suggests that even at the very young ages at motherhood, the fertility process is being affected by the educational process.[8] Further, there is longitudinal evidence showing a negative relation between educational aspirations and age at first birth (Marshall and Cosby, 1977; Card and Wise, 1978, Table 3), which suggests that many of those who have a first birth while they are of school age do so after deciding not to continue in school—and, perhaps, do so to justify dropping out of school. Finally, Haggstrom and Morrison (1979) find that among teenagers who do not drop out of high school, the effects of adolescent parenthood on subsequent educational aspirations are extremely small when other appropriate factors are controlled. All of this does not mean that fertility never truncates education, but only that it does so rarely. In the vast majority of the cases, education and educational aspirations determine age at first birth.

It is important that scientific discourse clarify the difference between a social policy concern that requires amelioration and the characterization of the overall process in which that concern is embedded.

Education and the Lengths of Birth Intervals

As discussed in the first section of this paper, we would expect to find a variety of reasons why women with more education would want to avoid very short birth intervals and we would expect them to be more effective at implementing their preferences. In this section we examine the relationship between education and the probability of having a short interbirth interval. Unlike the previous section, here, we assume that the direction of causality runs from education to the length of birth intervals.[9]

The birth history information contained in the 1970 NFS allows us to compute the length of each birth interval. Given the well-known difficulties involved in the analysis of birth intervals (see Bumpass et al., 1977, for a fuller discussion), we ini-

---

[7] Age at leaving school was computed by assuming a normal starting age, and assuming that education is obtained one year at a time.

[8] To further explore this issue, and to explore whether a gating mechanism existed, we reran the two-stage least squares analysis for women who became mothers at a young age. Although caution is necessary in interpreting such an analysis because the variance of the endogenous variables has been reduced, age at first birth does not have a significant effect on education.

[9] It should be noted, however, that it is possible that, for some women, short interbirth intervals prevent the return to school. Virtually nothing is known about returning to school after becoming a mother, although there has been some research on education after marriage. Approximately one in five women attend school after marriage; but the average addition to their educational attainment is relatively small: 1.0 years (Davis and Bumpass, 1976). Whether this schooling takes place before or after the start of childbearing is unknown. In order to minimize the possibility of education after the first birth being affected by the pace of fertility, we have primarily used education at marriage (rather than education at interview) for this analysis.

Table 3. Differentials in the Proportion Experiencing Birth Intervals of 18 Months or Less, for All Second, Third and Fourth Birth Intervals Begun 1959–1968, by Education, Gross and Net[a] Percentages: 1970 NFS

Education at Marriage	Second Birth Interval N	Gross	Net	Third Birth Interval N	Gross	Net	Fourth Birth Interval N	Gross	Net
Total	2612	25		2236	19		1551	17	
1–8	155	33	31	168	32	29	164	29	25
9–11	657	28	26	592	21	18	433	20	17
12	1218	24	23	1016	16	17	670	15	16
13–15	388	22	24	312	17	20	202	11	14
16+	194	20	29	149	16	21	82	13	18

[a] Adjusted through a dummy variable regression analysis for the effects of race, religion, region, age at first birth, marital status at first birth, contraceptive use before the first birth, planning status of first birth and smoking before age 16.

tially constructed life tables for each birth interval. These preliminary life tables were constructed for intervals begun in the period 1959–1968. By restricting the analysis to intervals begun in this period, we avoid a young-age-at-initiation bias (see Rindfuss and Bumpass, 1979).

The preliminary life table analyses showed the expected positive relationship between education and length of intervals. However, this conclusion is based on a bivariate analysis, and there are numerous other factors affecting the length of birth intervals (e.g., Bumpass et al., 1978), and the effects of these factors should be controlled. Unfortunately, the sample size of the 1970 NFS (or the 1973 FGS) is far too small to permit the simultaneous control of all these factors by using conventional life table techniques. Consequently, we used regression analysis to examine the probability of giving birth within a relatively short time interval—specifically, the probability of giving birth within 18 months of the previous birth. Because the life table results suggested that the differences in interbirth interval length are greater between adjoining categories at the lower educational categories than at the higher educational categories, we used a variant of multiple regression analysis, Multiple Classification Analysis (Andrews et al., 1973), to see if this pattern continued when other factors were controlled. The results are summarized in Table 3.

Controlling for other factors that affect the length of interbirth intervals eliminates much of the relationship between education and the probability of having a short birth interval. Compare the gross and net columns for the second, third and fourth birth intervals.[10] The difference which remains after controlling for other variables is primarily between those with a grade school education and all others. Given that those with only a grade school education are a small proportion of the population, and since the proportion with only a grade school education is declining, the principal result to emerge from Table 3 is that, when the effects of other factors are controlled, the respondent's education at first marriage has essentially no effect on the probability of having a short second, third or fourth birth interval.[11]

EDUCATION AND FERTILITY PREFERENCES

As discussed earlier in this paper, educational preferences and fertility preferences affect each other; and, since neither is fixed, their interrelationship develops over time. To examine adequately this complex set of interrelationships would require longitudinal data of the kind not currently available. However, in the absence of the appropriate longitudinal data, it is still possible to examine part of the process by looking at the effect of education at marriage on fertility preferences at time of interview. Framed this way, the causal direction is essentially unambiguous.

---

[10] We follow the standard convention of indexing birth intervals by the order of the fertile pregnancy terminating the interval. Thus, the second birth interval is the interval terminated by the second fertile pregnancy.

[11] The results in Table 3 are based on all birth intervals. Thus, both wanted or intended intervals and unwanted or unintended intervals are included. To make sure that the relationships shown in Table 3 were not the result of differences in fertility intentions, we calculated a set of life tables for "intended" intervals, excluding the following two types of intervals: (a) closed intervals that were closed by an unwanted birth, and (b) open intervals where the respondent indicates she does not intend to have another child. These results (not shown) are virtually identical to those shown in Table 3. Also, in order to see if the finding was sensitive to the particular measure of education used, we reran the analysis using respondent's education at interview, and then we reran it again using respondent's husband's education at respondent's first marriage. These alternative analyses lead to the same conclusions.

Education at marriage can affect fertility preferences in two ways. First, education at marriage can have a direct effect on fertility preferences. Insofar as increased education makes a larger variety of roles available to women, we could expect education to have a direct and negative effect on fertility preferences. In addition, specific topics covered while in school might have a direct negative effect on fertility preferences. Second, education at marriage can have an indirect effect on fertility preferences through its effect on age at first birth. As shown earlier, higher levels of educational attainment result in older ages at first birth. An older age at first birth, in turn, leads to longer intervals between births (Bumpass et al., 1978). Thus, education leads to older ages at any given parity; and older ages at any given parity have a negative effect on the probability of wanting another child (Rindfuss and Bumpass, 1978).

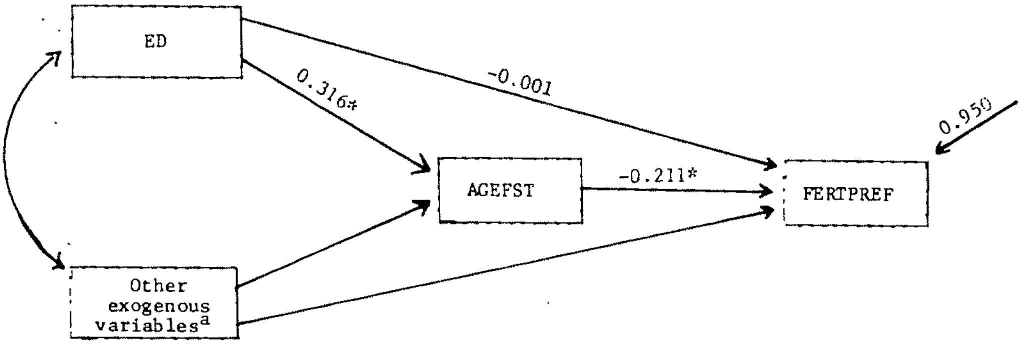
The measure of fertility preferences used here, FERTPREF, is the sum of the number of "wanted" children the woman had had by the time of the interview plus the additional number of children she intended to have. For each live birth, the woman was asked a series of questions to determine whether or not, before that child was conceived, she wanted to have a birth of that order at some time during her reproductive life (see Westoff and Ryder, 1977, for a more detailed description). Such a series of questions minimizes the possibility of post factum rationalization of unwanted births (Rindfuss, 1974). The additional number intended is obtained from a question asking the respondent how many additional children she intended. This fertility preference measure is coded in numbers of children and has a mean of 2.9, and a standard deviation of 1.5.[12]

Because one of our interests is in the mediating effect of age at first birth, the sample being analyzed is limited to mothers, that is, women who have had at least one live birth. As in the previous two sections, in order to allow women sufficient time to get married and have a first birth, younger women are excluded from the analysis. The analysis in this section, like the age at first birth analysis, will be restricted to respondents aged 35–44 at the time of the interview. Because the full set of questions used in constructing our fertility preference measure was not asked of postmarried women (i.e., those widowed, divorced or separated at the time of the interview), the analysis will be limited to currently married women. Finally, for ease of presentation, the set of exogenous variables to be used here, in addition to education at first marriage, is exactly the same as those shown in Figure 1 and described in Table 1. We have experimented with other sets of exogenous variables and with other definitions of the sample, and the results are similar in all cases.

The results are summarized in Figure 2. In order to focus on the education-fertility preference relationship, only the direct and indirect effects of education are shown. It can be seen that the direct effect of education on fertility preferences is trivial and insignificant. Virtually all of the effects of education at marriage on fertility preferences operates through age at first birth. Furthermore, the importance of age at first birth in influencing fertility preferences at time of interview should be underscored. Although it is not shown in Figure 2, age at first birth has a stronger direct effect on fertility preferences measured at time of interview than any of the listed exogenous variables. Thus, it appears that education affects fertility preferences by sorting women into various ages at first birth.

---

[12] It should be noted that there is little variance in fertility preferences. Three-fourths of the sample gave a preference of 2, 3 or 4. This, of course, reduces the possibility of any variable significantly affecting fertility preferences.



TOTAL EFFECT: ED → FERTPREF = -0.058

[a] The other exogenous variables in the model are: DADSOCC, RACE, NOSIB, FARMBACK, REGNBACK, ADOLFAM, RELIGION, YOUNGCIG, AND FECUND. See Table 1 for a description of the measurement of these variables.

Figure 2. A Model[a] of the Relationship between Education at Marriage and Fertility Preferences (Standardized Coefficients)[b]

For approximately four-fifths of these women, education at first marriage is the same as education at interview; but one-fifth of these women have attended school since their first marriage (Davis and Bumpass, 1976). For many women, this school attendance takes place a considerable time after the first marriage. For example, for women first married between 1951 and 1955 who returned to school after marriage, 62% last attended school 10 or more years after the first marriage. This additional schooling could affect fertility preferences, or could be affected by fertility preferences. We do not have the appropriate data to sort out these possibly reciprocal influences. But we did rerun the analysis in Figure 2 using education at interview instead of education at marriage, and the results are suggestive. The finding, as before, is that most of the relationships between education and fertility preferences operate through age at first birth. However, the direct relationship between education and fertility preferences is somewhat larger when education at interview is used than when education at first marriage is used. Without being able to sort out the potential reciprocal effects, we can only speculate that education after marriage operates to provide options that would not otherwise be available, or is itself a response to (or simultaneous with) a decision to terminate childbearing earlier than planned. This issue is something that warrants further examination.

CONCLUSION

To summarize, the reciprocal relationship between education and age at first birth is dominated by the effect from education to age at birth, with only a trivial effect in the other direction.

Once the process of childbearing has begun, education has essentially no direct effect on that process. Education has little direct effect on either the length of interbirth interval or on fertility preferences. Work by Vaughn and her colleagues (1977) shows that education has no direct effect on contraceptive efficacy. However, education has a significant indirect effect on these various components of fertility because it is the major determinant of age at the beginning of childbearing; in fact, education has a substantially greater influence on age at first birth than any other variable (Rindfuss and St. John, 1979). Thus, it is the postponing of motherhood that produces the oft-observed negative bivariate relationship between education and children ever born.

The powerful mediating effect of age at first birth is of interest in its own right. Older ages at first birth lead to longer interbirth intervals (Bumpass et al., 1978), more effective contraceptive use (Vaughn et al., 1977), and preferences for fewer children (as shown in the previous section of this paper).

These results, particularly if they are supported by future research on more recent cohorts, raise a set of interesting policy issues about which we can only speculate at present. Because the postponement of something is always more amenable to policy initiatives than its prevention, policies aimed at influencing age at first birth would be more likely to succeed than policies aimed at directly influencing children ever born. Furthermore, how adolescents spend their time has been accepted (although not universally) as something governments can legitimately influence—the military draft system is the most obvious example.

We began with the observation that a major way education might affect the roles women occupy is through altering the structure of childbearing experience, given the dominance of mother roles. We conclude that such educational effects as we can identify are explicable more in terms of education's effect on age at first motherhood than in terms of other values or aspirations that might derive from advanced schooling.

SOME EXPERIMENTAL INVESTIGATIONS OF THE PRINCIPLES OF DIFFERENTIAL ASSOCIATION THROUGH DELIBERATE MANIPULATIONS OF THE STRUCTURE OF SERVICE SYSTEMS*

D. A. ANDREWS
Carleton University

American Sociological Review 1980, Vol. 45 (June:448–462)

The paper reviews a series of examinations of three key principles of differential association: the contingency principle, the socioemotional principle, and the principle that criminal acts occur as a function of an excess of definitions favorable to violation of the law. The studies sampled a variety of correctional clients in a variety of correctional settings and in each there were explicit attempts to exert direct experimental control over the factors of theoretical interest as well as competing factors. In total, the findings support both the causal and the practical significance of differential association while documenting (a) structural effects on the contingencies within the service system, and (b) the effects of those contingencies on the criminal attitudes and behavior of individuals. The discussion critically contrasts such systematic testing of assumptions with related programs which have been operating for years with limited theoretical and practical returns. The paper suggests, in total, that systematic program evaluation provides the tools—and the opportunity—for a bridging of the gaps between general sociology and general psychology and between social science theory and social service.

This paper reviews a series of deliberate and explicitly experimental investigations of the causal and, hence, practical significance of certain principles of differential association theory (DA). The principles were divided into two broad sets: the conditions which promote criminal learning (differentials in exposure to criminal and anticriminal patterns within intimate personal groups) and the conditions under which criminal learning becomes evident in criminal behavior (criminal behavior occurs when there is an excess of favorable definitions). Since controlled variations in the learning conditions were induced by way of structural interventions, the studies also speak to DA's frequently applauded ability to provide a theoretically consistent perspective at both the structural and individual levels (Akers, 1973; Cressey, 1960). An additional feature is the suggestion and documentation of an operational means of examining the "excess" principle as well as a means of experimentally analyzing the causal significance of symbolic interaction of the intrapersonal kind. Finally, and hopefully without attempting to blind the reader to the obvious limits of the specific studies, the review relates to a number of more general and recurring issues in the social sciences: the need to narrow the gap between social science theory and the design and evaluation of social services; the potential of a behavioral orientation as a complement to the still-dominant perspectives of symbolic interactionism and group dynamics theory; and the potential of an explicit, yet theoretically consistent, interdisciplinary approach to program evaluation. The

The studies were funded by a number of different agencies over the last seven years: the Planning and Research Branch of the Ontario Ministry of Correctional Services; the Canadian Penitentiary Service, the Correctional Consultation Centre and the Research Division of the Ministry of the Solicitor General of Canada; the Law Reform Commission of Canada; the Canada Council and currently the Social Science and Humanities Research Council of Canada. Thanks to the many colleagues and students who have contributed to the studies—in particular, Don Kennedy, Steve Wormith, Colin Farmer, Flo Hughes, and Jerry Kiessling; and Wendy Daigle-Zinn, Judith Hughes, Marina Kouri, Gordon Young, Roberta Russell, David Wayne, Brian Grant and Susan Mickus. Among those correctional professionals whose cooperation made the studies possible, thanks in particular to Roger Dupuis, John Braithwaite, Bill Jackson, Mort Smyth, Frank Kaar, Gerry Brown, Paul Gendreau, Andy Birkenmayer, Leah Lambert, Jody Gomber, and, again, Jerry Kiessling. Thanks to the prisoners, probationers, and volunteers who participated in the programs and agreed to allow specifics of the programs in which they participated to be subject to random assignment.

paper opens with a summary of the current status of DA, reviews the series of investigations which test it, and closes with some recommendations and conclusions regarding DA and the more general issues just noted.

The Status of Differential Association: Toward Tests of Causal Significance

DA has been the preeminent perspective on criminal conduct for most of its 40 years (Sutherland, 1939; Sutherland and Cressey, 1970). Many have argued that its survival value has more to do with ambiguity and untestability than with intellectual rigor and empirical support (for a review see Nettler, 1978). Others have evaluated DA relative to its competitors and on this basis its survival appears to be that of the fittest (Akers, 1973; Cressey, 1960; Glaser, 1962). More recently, a number of cross-sectional and predictive validity studies have confirmed Glaser's (1962) contention that thoughtful attention to association with both criminal and anticriminal patterns would be rewarded by impressive gains in the predictability of criminal indices (Akers et al., 1979; Andrews et al., 1979; Buikhuisen and Hoekstra, 1974; Empey and Lubeck, 1971; Glaser, 1974; Harris, 1975; Linden and Hackler, 1973). However, the increasingly positive picture clouds when one looks for specific tests of causal and practical significance within an experimental (as opposed to descriptive) framework.

The promise of evidence regarding causal significance was inherent in systematic, empirical explorations of a "clinical sociology" (Cressey, 1955; Empey and Rabow, 1961), specifically, evaluations of guided group interaction (Empey and Erickson, 1972) and related programs (Hackler and Hagan, 1975) for delinquent or high-risk youths. The data are now in from a number of such experiments and the evidence is overwhelmingly clear. The massive and intrusive group and related programs were either no more effective or less effective than comparison programs such as routine individual probation supervision (Stephenson and Scarpitti, 1974). More disturbing than the negative results has been the utter failure of the evaluations to provide even one explicit and direct examination of the DA-based assumptions on which the programs were designed. Cressey (1955) stated that the focus of the programs should be the attitudes, values, and beliefs of groups rather than of individuals; and he adapted Cartwright's (1951) group dynamics principles to the correctional scene. For over 20 years, with the possible exception of Klein (1971), there was not one controlled test of the importance of group cohesion nor of the competing structural means of inducing an anticriminal focus within groups (Andrews, 1979a; 1979b).

The paucity of theoretical, empirical, and practical gains can be traced to two related factors. Just as Schwartz (1961) warned in this journal in his response to Empey and Rabow's (1961) guidelines for guided group interaction, the clinical sociology tradition has been characterized by an inattention to, or lack of appreciation of, the efforts of other disciplines. The lack of cross-discipline exchange is clearly evident, even today, when one examines how many respected sociologists have reacted to the negative outcome of the grand experiments. Schur (1973:170) advises that as long as treatment must be offered, then "available evidence favors emphasizing relatively unstructured group sessions." Hackler (1978) advises a deemphasis of controlled evaluation and more careful attention to basic principles governing human behavior. What principles?—"cognitive dissonance" and "group interaction." Stephenson and Scarpitti (1974) conclude (somewhat lamely) that some incidental learning has occurred regarding program implementation and that, hopefully, more will be learned in the future. The conclusion is inescapable that those who have worked in the symbolic interaction and group dynamics traditions have been unaware of, or uninterested in, the behavioral revolution that has occurred over the last 15 years in the delivery and evaluation of social services. The self-critical yet self-correcting behavioral literature includes an increasing number of controlled and positive evaluations of correctional programs (for reviews, see Andrews, 1979a; 1979b; Gendreau and Ross, 1978). The problem is not unlike that documented by Hirschi and Hindelang (1977) with reference to the inability of sociology to incorporate the well-documented relationship between IQ and delinquency.

A second and related reason for the failure of clinical sociology to advance significantly either understanding or service has to do with the style of the research. The evaluators compared structurally complex programs in terms of ultimate impact on recidivism without systematically documenting the effects of program structure on the actual process or contingencies of treatment, without documenting the relationship between process and the intermediate attitudinal gains thought to be mediating behavior change, and without documenting the extent to which the attitudinal gains (or losses) were associated with recidivism. The tenets of symbolic interactionism and group dynamics theory were accepted without challenge, as was the programmer's ability to create the appropriate conditions through structural means. Andrews and Kiessling (1979) have noted elsewhere the confusion possible when the links among structure, process, intermediate gain, and ultimate outcome are not specified and monitored.

Given this background of impressive heuristic and predictive value—yet an inadequate documentation of causal and practical significance—the most promising recent development has been the extension of DA's power and applicability through links with behavior theory (Adams, 1973; Akers, 1973; Andrews et al., 1974; Andrews et al., 1979; Burgess and Akers, 1966; and Howell's, 1972, use of Homans, 1961). Through behavioral reformulations, DA is freed from the descriptive and antiexperimental tradition of classical symbolic interactionism. The collections of Cressey and Ward (1969) and Rubington and Weinberg (1973) are probably most representative of that tradition in the study of deviance and, in the well-over-100 papers sampled, there is only one example of a controlled experimental study. The behavioral orientation is strongly experimental, yet not insensitive to the potential of descriptive investigations or to other methodologies (Bijou et al., 1968). It is much more flexible and open to cognitive factors (Bandura, 1969; Meichenbaum, 1977) than its most derisive and ideologically committed critics in the area of deviance (Taylor et al., 1973) would have us believe. It promises, indeed demands, the systematic and empirical examination of DA's most basic tenets without necessarily severing ties to models—both of man and of behavioral influence—which emphasize reason and choice as well as interpersonal concerns.

The purest (and yet the weakest) of the operant reformulations of DA is that of Adams (1973). He systematically purged DA of any "mentalistic concepts," deemphasized the social nature of the learning and performance processes, and, in short, produced what Nettler (1978) would call a "true but trivial" statement. Statements to the effect that the acquisition, maintenance, and modification of criminal and noncriminal behavior are governed by similar principles do not constitute a theory of criminal behavior. They are statements concerning a general theory of behavior. Similarly, empirical documentations of the fact that the criminal and noncriminal behaviors of offenders and nonoffenders are under antecedent and outcome control do not constitute convincing support for a behavioral version of DA. Such demonstrations expand the literature on the applicability of behavioral principles and techniques to corrections, but they do not meaningfully advance our understanding of the causal significance of DA principles.

Experimental evidence relevant to DA, regardless of the theory and technology of behavioral influence associated with it, should involve tests of one or more of the key principles. The following principles are the ones investigated in the series of studies to be reviewed:

(a) Criminal learning occurs by way of association with criminal patterns and relative isolation from anticriminal patterns. In behavioral terms, this is the contingency factor and refers to the criminal versus anticriminal nature of the patterns to which the individual is exposed (modeling) and the consequences for the individual (reinforcement and punishment) of exhibiting criminal and anticriminal patterns (Andrews et al., 1974).

(b) The principal part of learning occurs within intimate personal groups. This is the quality of interpersonal communication factor or the socioemotional/relationship factor. In behavioral terms, the most effective model is one who, among other things, controls a wide variety of high-quality reinforcers (or punishers) and who rewards the other for exhibiting demonstrated behaviors (Bandura, 1969). We will assume that the dimensions on which "intimate personal groups" are defined are the same dimensions on which variations in the reinforcing and punishing value of another's response may be classified (Homans, 1961). For example, an interpersonal situation characterized by mutual liking and respect, and by understanding and open communication is an "intimate" one, one within which the behaviors of the other are attended to (with the potential of enhanced modeling effects), and one in which the other is a potential source of powerful reinforcers and punishers.

(c) A person engages in criminal acts ("becomes criminal") when there is an excess of definitions of the situation favorable to violation of the law over definitions of the situation unfavorable to violation of the law. In behavioral terms, this is the self-management factor, a subset of the more general factor of discriminative stimulus control over criminal acts. There may well be situations or individuals wherein, or for whom, the objective properties of the immediate situation discount any set of motives, rationalizations, or beliefs which the individual brings with him (Wells, 1978), but that is not the concern of the studies reviewed. We assume that the products of the learning which has occurred by way of the contingency and relationship factors—products in the measurable form of attitudes, values, and beliefs—may (in some situations and under some conditions) be causally associated with criminal performance. Generally, there will be a greater correspondence between cognitions and behavior among individuals who engage in self-monitoring, self-instructing, and self-consequating than among individuals who less systematically practice such measurable and trainable self-management skills (Bandura, 1969; Meichenbaum, 1977).[1]

In summary, the contingency and relationship principles have to do with the conditions under which criminal learning occurs, while the self-management principle has to do with the conditions under which criminal learning is translated into criminal acts. The causal implications of these principles may be inferred from controlled studies in which (a) deliberately induced variations in the learning situation are monitored for effects on criminal learning and, (b) deliberately induced shifts in the balance of favorable and unfavorable definitions are monitored in relation to criminal activity. Of particular interest to the general sociologist is the fact that the variations on the contingency and relationship dimensions may be induced through structural interventions within those miniature social systems which constitute the specific settings for intervention. Mayer (1972) has provided a compelling analytic base for the investigation of structural approaches to social problems, but, reflecting the state of the art and the science, he did not present one experimentally derived example. In the studies reviewed here, the dominant interventions were those of changing the membership composition of the treatment system and/or changing the role composition of the systems.

The value of any empirical study depends upon how well the factors of theoretical interest—as well as competing factors—have been brought under experimental control. Since it is naive to expect that any single study could discount all competing factors or could introduce simultaneous controlled variation on all factors of theoretical interest, integrated research programs—rather than isolated studies—are indicated. Each study, within the set to be reviewed, made a systematic attempt to control for competing factors not well attended to by other studies in the set and/or to induce systematic variation in relevant factors which had been held constant in the other studies. In addition to such general problems of internal validity, there are also problems of external validity which can be dealt with only through systematic replication and extension to different types of subjects, settings, manipulations, and measures. Explicit attempts were made to sample from different settings and subject groups, but there are three obvious limits on generalizability: all of the studies involved official offenders who were serving formal sentences at the time of the studies; every study made use of the same attitude battery—a positive feature in terms of comparability within the set, but a negative feature in terms of external generalizability; and all studies were completed by the same research team—or at least by a professionally related group of researchers. Regarding the second limitation, we find that some of the studies have supplemented the attitudinal measures with recidivism data.

---

[1] The designation of differential association or DA is used throughout this paper to refer to these principles. However, readers familiar with differential association literature will recognize that it is the behavioral reformulation that is being tested here, rather than strictly the original theory as stated by Sutherland. The behavioral reformulation as stated above adds three elements to the original: the specification of modeling and reinforcement in the "contingency factor"; the linking of "intimacy" to the schedule and quality of modeling and reinforcement; and the linking of the causal significance of "definitions" to discriminative stimulus control through self-management.

The Contingency Principle

The first set of studies involved evaluations of a coparticipant role for student and citizen volunteers in institution-based group counseling with the adult-male residents of two minimum-security prisons. Prior to these studies, several controlled evaluations of short-term structured group counseling had produced evidence that groups composed of prisoners and a nonprisoner leader were having effects on various attitudes and behaviors, including institutional adjustment (Andrews and Young, 1974), interpersonal skills and self-esteem (Daigle-Zinn and Andrews, forthcoming), and knowledge of legal rights (Wayne and Andrews, 1978). However, Wayne and Andrews (1978) were unable to obtain effects on the attitudinal measures most obviously relevant to the notion of definitions favorable versus unfavorable to violations of the law—that is, on measures having to do with respect for the law, courts, and police; with tolerance for law violations; and with identification with offenders. It appeared that the differentials in the quality of exposure to criminal and anticriminal expressions (differentials so well-documented by Buehler et al. [1966] at a girl's training school) were also present in our counseling groups. Thus, a structural change was introduced for those counseling groups which focused upon attitudes and beliefs regarding the law and law violation—specifically, a change in membership composition through the introduction of noncriminal others as codiscussants.

The Community Groups involved from four to seven citizen volunteers (primarily college students) and from four to seven prisoners, interacting for one evening a week for a period of eight weeks. Each group had a nonresident leader whose operational guidelines were to encourage open, warm, and frank communication while structuring discussions around preselected topics such as the function of rules, the validity and limits of common rationalizations for law violations, and a social learning perspective on self-control. All participants had responded to announcements at their respective institutions that Community Groups were being established. Details on the institutional settings and group procedures have been provided elsewhere (Andrews et al., 1974; Andrews and Gendreau, 1976).

The first study (Andrews et al., 1973) suggested that the Community Group model provided not only a potentially important service but also a vehicle for the systematic evaluation of the causal significance of DA. Inspection of the Client factor in Table 1 shows that the volunteers and prisoners differed, first, in the expected (and theoretically relevant) ways on the attitudinal measures of respect for the law, courts, and police; tolerance for law violations; and identification with criminal others. Secondly, participating residents showed reduced tolerance for law violation and reduced identification with offenders, at posttest, relative to a nonparticipant comparison group of residents, while the participating citizen volunteers were showing increased identification with criminal others relative to a waiting-list control set of volunteers. The triple interactions presented in Table 2 have since been replicated in detail by

Wormith (1977). However, our first study did not directly vary exposure to anticriminal patterns—a more crucial element of Sutherland's theory than exposure to noncriminal others—and, by virtue of the use of nonparticipant controls, the changes may simply have reflected an attention-placebo or demand effect.

The second study (Andrews et al., 1977) was an explicit attempt to hold attention and association with noncriminal others constant while varying the opportunity for the exposure of anticriminal patterns. Volunteers and prisoners were randomly assigned to either a Community Discussion Group (codiscussant roles) or a Community Recreation Group (companion roles). In the latter, the participants engaged in various table-top games with no programmed opportunity to expose their sentiments regarding the law. There was a built-in replication with residents drawn from the two physically separate institutions which were located on the same grounds, one for first incarcerates and the other for recidivists.

Table 3 provides a summary of the analyses of variance in attitude change (postscores minus prescores). Within both institutional samples, any statistically reliable attitudinal gains on the indices of definitions unfavorable versus favorable

to law violations were found following participation in the discussion groups but not found following participation in the recreation groups (Table 4). In fact, the changes found among prisoners in the recreation condition were no different from those found within a waiting-list control group of prisoners. Overall, the findings discounted an effect due to attention or to simple exposure to noncriminal others but, given the focused nature of the discussion condition, there was still the possibility of a Testing × Treatment interaction.

The Relationship Principle

The third study (Andrews et al., n.d.[b.]) was an experimental investigation of the socioemotional factor as well as an attempt to discount the possibility of a Testing × Treatment interaction. All residents participated in focused discussion groups, but the specific groups to which they were randomly assigned varied in terms of the interpersonal skills of participating citizens. Goodman's (1972) behavioral assessment technique was employed to obtain preassignment measures on the volunteer's openness, warmth, and understanding as rated by peers. Two types of Community Groups were formed, one including citizens who were above the median on peer ratings and the other including citizens who received below average peer ratings.

Table 5 provides a sample of the findings from the third study. The membership composition manipulation was effective in influencing the socioemotional climate in that the more-skilled volunteers and the prisoners in their groups reported

Table 5. The Effects of the Interpersonal Skills Level of Volunteers on the Socioemotional Climate and Interaction Process Within Groups and on Changes in the Criminal Sentiments of Prisoners (Study III)

	Groups With the Less Skilled Volunteers. (Prisoners $n=18$; Volunteer $n=20$)		Groups With the More Skilled Volunteers. (Prisoner $n = 18$; Volunteer $n = 21$)

Tolerance for Law Violations a	2.9	5.7	−4.7	8.1	5.72	.03
b	−2.4	2.3	1.0	4.5	4.22	.05

Note: There was a statistically reliable Interpersonal Skill × Prisoner Anxiety interaction on the Tolerance change scores, F (1/32) = 8.81, $p<.006$. Similar interactions on the Law and Identification scales failed to reach reliable levels. The "a" values are for low anxiety prisoners; the "b" values, for high anxiety prisoners.

more open and emotionally frank communication than did the less-skilled volunteers and their prisoner coparticipants. The two types of groups did not differ on the Bales's (1950) interaction process measure of expressed opinions but, as indicated in Table 5, apparently the volunteers and residents in the less-skilled groups had to make more direct requests for the expression of personal opinions. The skilled volunteers were more likely to take a leadership role in the discussions by offering suggestions than were the less-skilled volunteers. Note that successful manipulation of the relationship factor was completed without concomitant variation of the contingency factor, in that peer ratings on interpersonal skills were statistically independent of the volunteers' pretested scores on the criminal orientation measures.

The outcome supported the relationship principle—particularly among those prisoners who were below the resident average on a pretested trait measure of anxiety (Table 5). Generally, the posttreatment changes on the attitudinal measures of a criminal orientation were most strongly in the anticriminal direction among those prisoners who had interacted with the more interpersonally skilled volunteers. However, it appeared that the confrontation format may have been dysfunctional with the more anxious residents, a finding anticipated by other group programs (Sarason and Ganzer, 1973).

The third study provided an additional opportunity to examine the relationship principle, an opportunity which was not reported in Andrews et al. (n.d.[b.]). At the end of the next-to-last session of the groups, individual volunteers and prisoners were asked to report on the extent to which there had been obvious divisions between volunteers and prisoners during the sessions. A group-dynamics perspective (Cressey, 1955) and social learning theory yield the prediction that the *amount* of attitude change would be a positive function of cohesion. However, the more interesting question is whether the *direction* of the relationship between cohesion and change depends upon the type of client. The first study (Tables 1 and 2), in conjunction with the contingency principle, had suggested that volunteers and prisoners tend to become more alike in their criminal sentiments as a function of exposure to each other. According to the relationship principle, the prisoners should become more anticriminal in their attitudes, under association conditions of high perceived cohesion, while the citizen volunteers should move toward less anticriminal positions. An examination of the correlations between perceived cohesion and attitude change suggested that just such an interaction was present. The correlation of cohesion with changes in the tolerance for violations measure was $-.35$ ($p<.05$) within the prison sample but .26 ($p<.10$) within the volunteer sample. For changes in identification with offenders, the correlations were $-.33$ ($p<.10$) and .34 ($p<.05$) for the prisoners and volunteers respectively.

The Interaction of the Contingency and Relationship Principles

The studies had shown that anticriminal learning on the part of prisoners was a function of programmed differentials in the exposure of criminal and anticriminal patterns and that anticriminal learning was most evident under program conditions designed to promote positive interpersonal interactions. What was required was an examination of impact when the contingency factor and the socioemotional factor varied in combination. Specifically, DA predicts that there is a positive or negative relationship between the socioemotional factor and criminal learning, depending upon the relative exposure of criminal and anticriminal patterns.

The fourth study (Andrews et al., forthcoming) was conducted in two medium-security penitentiaries and involved adult recidivists serving sentences of over two years. The prisoners were randomly assigned to two types of groups: one, of the Community Group format; and the other, a discussion group focusing on the same topics but without citizen volunteers as coparticipants. Table 6 presents a summary of the findings. Important to the research program—but not unexpected—was the finding that the volunteers, known to be more anticriminal in

Table 6. The Effects of Volunteer Participation on the Socioemotional Climate and the Anticriminal Contingencies Established Within Groups, on Changes in the Criminal Sentiments of Prisoners, and on the Correlations between Socioemotional Climate Ratings and Changes (Study IV)

	Community Groups				Resident Groups				*F*
Socioemotional Climate									
(Prisoners' Ratings)									
Openness (Institution A)	13.50				10.43				6.35*
Openness (Institution B)	11.75				16.75				17.98**
Procriminal Arguments	1.63 (Volunteers)				2.63 (Residents)				34.91**
Prisoner Attitude Change									
Law, Courts, Police (Institution B)	.25				−9.75				7.98*
	Partials				Partials				
Openness Ratings in relation to Attitude Change	*r*	r^a	r^b	r^c	*r*	r^a	r^b	r^c	*Z*
Law, Courts, Police	.89**	83	86	85	−62	−56	−47	−29	3.24***
Tolerance for Law Violations	−75**	−61	−79	−88	34	30	28	48	1.94*

* $p<.05$.
** $p<.01$.
*** $p<.001$.

Note: See text for discussion of interactions (Prisoner N=16; Volunteer N=16).

their pretested attitudes, did in fact express more anticriminal sentiments within the groups than did the prisoners. During selected sessions participants were asked to provide arguments favorable versus unfavorable to specific violations, such as illegal parking, burglary, and armed robbery. Content analyses of typed transcripts prepared from videotaped portions of these sessions confirmed that the arguments of the prisoners were more favorable to each of the three types of violations than were those of the volunteers. Note that the presence of the volunteers had no detectable effect on the expressed arguments of the prisoners during the groups' meetings, but it was the case that anticriminal sentiments had a greater exposure within the Community Groups than within the Resident Groups.

The effects of volunteer presence on the socioemotional climate and on prisoner attitude change were less clear. Within one of the institutions, the presence of volunteers was associated with more open and frank discussion, according to the ratings by prisoners; the effect was exactly opposite within the other institution. Similarly, the effects on prisoner attitude change were less than impressive. In only one of the institutions, and on only one of the criminal sentiment scales, was there a statistically reliable effect of volunteer presence. However, the impact of the two types of groups on the relationship between socioemotional indices and attitude change was more crucial to DA theory than was the impact of the groups on either, separately. Inspection of the correlations in the bottom portion of Table 6 reveals that interaction predicted by DA was evident. Within the resident-only discussion groups, the groups in which the criminal expressions had been less well-balanced by anticriminal expressions, positive prisoner evaluations of the socioemotional evaluations were associated with procriminal changes on the attitude measures. Within the Community Groups, positive socioemotional evaluations were associated with anticriminal changes. The reversal of effects, dependent upon type of group, was evident within both institutions and remained when statistical controls were introduced for prescores and any generalized tendency to "fake good."

Given the consistency of the above set of findings, from study-to-study and with reference to DA, it was time to manipulate experimentally both the relationship and the contingency factors and to monitor effects on behavioral indices. In conjunction with an attempt to produce a broad comparison of the volunteer and professional supervision of adult probationers (Andrews et al., 1979), the volunteers (n = 60) and professionals (n = 14) were pretested on a number of self-report attitude and personality scales, including three which were relevant to the contingency and relationship factors implicated by DA: the Hogan Empathy (EMP) scale which has excellent psychometric credentials as a measure of interpersonal skills (Grief and Hogan, 1973); the Gough (1969) Socialization (SOC) scale which is one of the more reliable and valid personality predictors of criminal activity and, hence, a solid measure of a conventional orientation; and the measure of Identification with Criminal Others (ICO) which had been successfully employed in the Community Group studies and whose positive correlation with the Hogan Empathy Scale had been discovered with volunteers in still another study (Andrews et al., n.d.[a.]). The prediction was now obvious: the most effective probation officers would be those who were interpersonally skilled (above the median on EMP), conventional in orientation (above the median on SOC), and not too enamored of criminal others (below the median on ICO).

Probationers (n = 190) were randomly assigned to either a volunteer or professional officer, and to officers within each category without reference to the officers' scores on EMP, SOC or ICO. The managers of the probation program, the officers and their clients, and the research staff were "blind" with reference to the personality scores of the officers prior to case assignment, as well as during the supervision and data collection periods.
